ABSTRACT

Combinatorially obtained minimal Cantor sets are acquired as the inverse limit of certain directed topological graphs where specific nonnegative integer matrices, called winding matrices, are used to describe the projection between each graph.

Examples of non-uniquely ergodic combinatorially obtained minimal Cantor sets first appeared in the 2006 article *Algebraic topology for minimal Cantor sets* of Gambaudo and Martens and are constructed using winding matrices whose entries grow “fast enough.” In this work, we will introduce families of minimal Cantor sets which may be combinatorially obtained in such a way that the corresponding winding matrices possess unbounded entries given by explicit sequences of nonnegative integers. For each of these families, the growth rate needed to achieve either unique or non-unique ergodicity will be specifically addressed and the result will be applied to the case of minimal Cantor sets corresponding to Lorenz maps.

We will explore the construction of topological semi-conjugations between combinatorially obtained minimal Cantor sets. Theorems guaranteeing the existence of a topological semi-conjugation between specific families of these sets will be proved and utilized to introduce examples possessing additional intriguing properties. We will also show that there exist both finitely and infinitely non-uniquely ergodic minimal Cantor sets semi-conjugated to an adding machine in such a way that the semi-conjugation map is almost-everywhere injective with respect to the unique ergodic invariant probability measure on the adding machine. Furthermore, we will prove that this construction can be realized by the dynamical system $(\omega(c), q)$ where q is a logistic unimodal map with critical point c and omega-limit set $\omega(c)$.

ACKNOWLEDGMENTS

I would like to begin by thanking my major advisor, Dr. Araceli Bonifant, who has gone above and beyond that which is required from her as a teacher and mentor. I am truly grateful for the opportunities she has provided, her continued support, her friendship, and her tireless commitment to my development as a mathematician and to the research contained within this dissertation.

I would also like to thank Dr. Marco Martens of Stonybrook University for generously sharing his research ideas, expertise, and time. Without Dr. Martens' selfless involvement, this dissertation would not be possible.

Dr. Orlando Merino, Dr. Mercedes Rivero-Hudec, Dr. Mustafa Kulenović, and Dr. Liliana Gonzalez graciously served on my committee. I would like to thank them along with Dr. Michael Barrus and Dr. Thomas Sharland for their questions, comments, and suggestions. I deeply appreciate the time they have given to improve this work.

I owe a separate thanks to Dr. Merino, whom I hold in the highest regard as a mathematician, educator, mentor, and person. I appreciate the refreshingly honest, sometimes humorous, and always patient advise, support, and caring he has provided throughout my graduate career.

I would like to thank the University of Rhode Island Mathematics Department for the abundance of opportunities over the past six years, and I would especially like to thank Dr. Kulenović for involving me in his research.

I would not be the mathematician, educator, or person I am today without those peers from my undergraduate and graduate studies who created a community of camaraderie and encouragement. For this and so much more, I thank them.

Thanks is also owed to my family and friends for their unfailing faith and support. I would especially like to acknowledge the advisors of Venturing Crew 1

Gardner and the faculty of the Fitchburg State University Mathematics Department. Most of all, I would like to thank my husband, Alexander Denette, for being both by my side and on my side since long before this journey began.

My last thanks is reserved for my colleague Addie Armstrong. It is a rare thing to find a friend that is willing to take every step with you on the challenging and often uncertain path that is life. I consider myself among the most fortunate of individuals to have had Addie choose to walk with me.

DEDICATION

To my dad

Master Chief Daniel Farrell (USCG)

CHAPTER 1

Introduction and Preliminaries

1.1 Introduction

In 1883, Cantor introduced the now well-known *middle-thirds Cantor set* within a footnote to his paper *Über unendliche, lineare Punktmanichfaltigkeiten* (see [1, Part 5]). One method of constructing this set begins by taking $A_0 = [0, 1]$ and then deleting the open middle third of this interval to obtain $A_1 = [0, \frac{1}{3}] \cup [\frac{2}{3}, 1]$. The set A_2 is formed by deleting the open middle third from each of the disjoint intervals that make up A_1 . In general, the set A_n ($n \geq 1$) is formed by deleting the open middle third from each of the disjoint intervals that make up A_{n-1} . The sets A_0, A_1, A_2 , and A_3 can be seen in Figure 1. The middle-thirds Cantor set \mathcal{C} is defined as the intersection of the sets A_n ; that is, $\mathcal{C} = \bigcap_{n=0}^{\infty} A_n$.

The middle-thirds Cantor set possesses a number of interesting properties. It is clearly nonempty (for instance, it contains 0). It is bounded and, as the intersection of closed sets, it is closed (hence compact). It also contains no intervals since the complement $[0, 1] \setminus \mathcal{C}$ has Lebesgue measure one. Furthermore, it is a perfect set since it is a closed set with no isolated points. This can be verified by observing that any $x \in \mathcal{C}$ lies in exactly one of the maximal disjoint intervals of length $(\frac{1}{3})^n$

Figure 1. An illustration of the construction of the middle-thirds Cantor set.

that make up A_n , say A_n^x . If x is not an endpoint of the interval A_n^x , take x_n to be the lefthand endpoint of A_n^x . Otherwise, take x_n to be the endpoint of A_n^x that is not x . Since endpoints are never deleted, $x_n \in \mathcal{C}$ for each n . Moreover, $x_n \neq x$ and $|x - x_n| \leq (\frac{1}{3})^n$ for each n . It follows that x is not isolated.

A generalization of the properties of the middle-thirds Cantor set allows for the definition of a *Cantor set*.

Definition 1.1. A *Cantor set* is a compact metric space that is totally disconnected and perfect.

Cantor sets arise frequently in the study of dynamical systems, where we are interested in determining the behavior of each point $x \in X$ under iteration of a given function $f : X \rightarrow X$. For $n \in \mathbb{N}$, the notation $f^n = f^{\circ n} = \underbrace{f \circ \dots \circ f}_{n \text{ copies of } f}$ is used, so for each $x \in X$, the sequence of interest can be written as

$$x, f(x), f^2(x), f^3(x), \dots$$

The set of points $\{x, f(x), f^2(x), f^3(x), \dots\}$ is called the *orbit* of x .

Example 1.2. The set of maps $T_a : \mathbb{R} \rightarrow \mathbb{R}$ defined by

$$T_a(x) = \begin{cases} ax, & x < \frac{1}{2} \\ a(1-x), & x \geq \frac{1}{2} \end{cases}$$

for $a > 0$ are called *tent maps*. Consider the tent map T_3 pictured in Figure 2. All points $x \in (-\infty, 0) \cup (1, \infty)$ tend toward $-\infty$ under iteration of T_3 ; such points are said to escape to $-\infty$.

Because of this, the set consisting of those points that do not escape to $-\infty$ under iteration of T_3 must be a subset of $[0, 1]$. It will be shown that this set is precisely the middle-thirds Cantor set.

As can be seen in Figure 2, the set of points $\{x : T_3(x) \in [0, 1]\}$ is given by $[0, \frac{1}{3}] \cup [\frac{2}{3}, 1]$ and the set of points $\{x : T_3(x), T_3^2(x) \in [0, 1]\}$ is given by

Figure 2. Plots of T_3 and T_3^2 on the interval $[0, 1]$ for the tent map T_3 defined in Example 1.2.

$[0, \frac{1}{9}] \cup [\frac{2}{9}, \frac{1}{3}] \cup [\frac{2}{3}, \frac{7}{9}] \cup [\frac{8}{9}, 1]$. Continuing in this fashion, we obtain that the set of points that do not leave the interval $[0, 1]$ under any iterate of T_3 (and hence do not escape to $-\infty$) is exactly the middle-thirds Cantor set.

Definition 1.3. A dynamical system (X, f) where X is a compact topological space and $f : X \rightarrow X$ is a continuous map is called *minimal* if every orbit is dense in X . If X is a Cantor set, the system (X, f) is called a *minimal Cantor set*.

Such minimal systems were originally defined and explored by Birkhoff in 1912 (see [2]), and have garnered a great deal of attention in the literature ever since. Minimal Cantor sets, in particular, often appear in the study of dynamical systems associated with unimodal maps.

Definition 1.4. A *unimodal map* is a map $u : [0, 1] \rightarrow [0, 1]$ satisfying $u(0) = u(1) = 0$ and for which there exists a point $c \in (0, 1)$ (called the *critical point*) such that u is increasing to the left of c and decreasing to the right of c .

Definition 1.5. For a fixed unimodal map u with critical point c , the *omega-limit set* $\omega(x)$ of a point $x \in [0, 1]$ is defined by

$$\omega(x) := \{y \in [0, 1] : u^{n_\ell}(x) \rightarrow y \text{ for some } n_1 < n_2 < \dots\}.$$

For a given unimodal map $u : [0, 1] \rightarrow [0, 1]$ with critical point c , the omega limit set $\omega(c)$ is compact and satisfies that $u(\omega(c)) = \omega(c)$. The set $\omega(c)$ may be a cycle of intervals, a Cantor set, a finite set, a countable set, or the union of a Cantor set and a countable set. Unimodal maps under which the omega-limit set of the critical point is a minimal Cantor set are known to exist and have been studied widely (see, for instance, [3, 4, 5, 6, 7]). The most well-known examples include the Feigenbaum map (see [8]) and the Fibonacci map (see [5]), which will be described in more detail in Chapter 4.

1.2 Combinatorially Obtained Minimal Cantor Sets

In 2006, Gambaudo and Martens gave conditions under which a minimal Cantor set can be obtained via the inverse limit of particular directed topological graphs (see [4]). In their article, the authors introduced the concept of using specific nonnegative integer matrices, called *winding matrices*, to describe the projection between each of these graphs. This section provides a summary of these and related results.

Definition 1.6. Let Y_1, Y_2, \dots be a countable collection of topological spaces and suppose that for each $n \in \mathbb{N}$ there exists a continuous mapping $g_n : Y_{n+1} \rightarrow Y_n$. The sequence of spaces and mappings $\{Y_n, g_n\}_{n=1}^\infty$ is called an *inverse limit sequence* and may be represented by the diagram

$$Y_1 \xleftarrow{g_1} Y_2 \xleftarrow{g_2} \dots \xleftarrow{g_{n-1}} Y_n \xleftarrow{g_n} Y_{n+1} \xleftarrow{g_{n+1}} \dots$$

For $n < m$, the continuous mapping $g_{mn} : Y_m \rightarrow Y_n$ is given by

$$g_{mn} = g_n \circ g_{n+1} \circ \dots \circ g_{m-2} \circ g_{m-1}.$$

Definition 1.7. The *inverse limit* of an inverse limit sequence $\{Y_n, g_n\}_{n=1}^{\infty}$ is given by

$$\varprojlim_{g_n} Y_n = \left\{ (y_1, \dots, y_n \dots) \in \prod_{n=1}^{\infty} Y_n : g_{mn}(y_m) = y_n \text{ for all } n \leq m \right\}.$$

Note that as a subset of the product space $\prod_{n=1}^{\infty} Y_n$ carrying the product topology, the inverse limit $Y = \varprojlim_{g_n} Y_n$ may be equipped with the corresponding subspace topology.

Definition 1.8. A *graph* is an ordered pair $G = (\mathcal{V}, \mathcal{E})$ comprised of a set \mathcal{V} of *vertices* together with a set \mathcal{E} of *edges* which are unordered, 2-element subsets of \mathcal{V} .

We will consider only those graphs for which each edge $\{U, V\}$ satisfies that $U \neq V$.

Definition 1.9. A *directed graph* will consist of a vertex set \mathcal{V} , an edge set \mathcal{E} , and a function assigning to each edge $e = \{U, V\} = \{V, U\}$ an ordered pair of its associated vertices. If this ordered pair is (U, V) the direction of e is considered to be from U to V , while if it is (V, U) the direction of e is considered to be from V to U . A *directed path* in a directed graph is a sequence of edges

$$e_1 = \{V_1, V_2\}, e_2 = \{V_2, V_3\}, \dots, e_n = \{V_{n-1}, V_n\} \quad (\text{for } n \geq 2)$$

where all edges are oriented in the same direction.

Gambaudo and Martens introduced an inverse limit sequence in which each topological space consists of a specific type of directed topological graph.

Definition 1.10. A directed topological graph G is called a *combinatorial cover* if the following three properties are satisfied:

1. The graph G is finite and the set of vertices carries the discrete topology.
2. The graph G is irreducible (any pair of distinct vertices is connected by a directed path).
3. Except for one vertex $0_G \in G$, each vertex of G has exactly one outgoing edge. The vertex 0_G is called the *splitting vertex*.

Definition 1.11. In a combinatorial cover G , a vertex $U \in G$ is called an *image* of a vertex $V \in G$ if there is a single directed edge from V to U . The shortest directed path from a vertex $V \in G$ to 0_G is called the *path of V* and is denoted by $\lambda(V)$. Furthermore, if U is an image of 0_G , then $\lambda(U)$ together with the directed edge from 0_G to U is called a *loop of G* . When the meaning is clear, the notation $\lambda(U)$ will also be used to denote such a loop.

An illustration of a combinatorial cover and these concepts can be seen in Figure 3.

In order to take the inverse limit involving a sequence of combinatorial covers, it is necessary to define a particular type of mapping between two combinatorial covers.

Definition 1.12. Let G and H be combinatorial covers. A map $\pi : G \rightarrow H$ is called a *combinatorial refinement* if the following three properties are satisfied:

1. The map π preserves the graph structure.
2. The map π satisfies that $\pi(0_G) = 0_H$; that is, the splitting vertex of the graph G is mapped to the splitting vertex of the graph H .
3. For each image $1_H \in H$ of the splitting vertex $0_H \in H$ there

Figure 3. An illustration of a combinatorial cover. Note that U_1 , U_2 , and U_3 are the images of the splitting vertex 0_G . The path of U_2 , $\lambda(U_2)$, is indicated by the dashed edges.

exists an image $V \in G$ of the splitting vertex $0_G \in G$ such that

$$1_H = \pi(V).$$

Lemma 1.13. (Gambaud & Martens) *Consider an inverse limit sequence consisting of combinatorial covers $\{G_n\}_{n=1}^\infty$ and corresponding combinatorial refinements $\{\pi_n : G_{n+1} \rightarrow G_n\}_{n=1}^\infty$. The corresponding inverse limit is a topological graph*

$$G = \varprojlim_{\pi_n} G_n$$

whose edges can be described by a continuous map $f : G \rightarrow G$.

Definition 1.14. Suppose the map f and graph G are as in Lemma 1.13. If the dynamical system (G, f) is a minimal Cantor set it is called a *combinatorially obtained minimal Cantor set*.

It is only natural to ask what restriction(s), if any, must be placed upon an inverse limit sequence of combinatorial covers and combinatorial refinements in

order to guarantee that a combinatorially obtained minimal Cantor set will result. The answer to this question requires the definition of a *winding matrix*.

Definition 1.15. For G_n and G_{n+1} combinatorial covers and $\pi_n : G_{n+1} \rightarrow G_n$ a combinatorial refinement, let $\{U_1, \dots, U_r\}$ be the images of the splitting vertex 0_{G_n} and $\{V_1, \dots, V_s\}$ be the images of the splitting vertex $0_{G_{n+1}}$. The $r \times s$ matrix W_n with entries

$$w_{ij} = \#\{A \in \lambda(V_j) : \pi_n(A) = U_i\}$$

is called the *winding matrix corresponding to π_n* .

Note that w_{ij} gives the number of distinct vertices in the loop $\lambda(V_j) \in G_{n+1}$ that are projected to the vertex $U_i \in G_n$ under the combinatorial refinement π_n . Equivalently, w_{ij} gives the number of times the loop $\lambda(V_j) \in G_{n+1}$ is wrapped around the loop $\lambda(U_i) \in G_n$ under π_n .

Example 1.16. Suppose that for some n the projection between the combinatorial covers G_{n+1} and G_n as pictured in Figure 4 has corresponding winding matrix

$$W_n = \begin{pmatrix} 2 & 1 & 3 \\ 1 & 3 & 0 \end{pmatrix}.$$

This matrix describes the projection in the following manner: The outermost loop of G_{n+1} is wrapped twice around the outer loop of G_n and once around the inner loop of G_n . The middle loop of G_{n+1} is wrapped once around the outer loop of G_n and thrice around the inner loop of G_n . The innermost loop of G_{n+1} is wrapped thrice around the outer loop of G_n and zero times around the inner loop of G_n .

Theorem 1.17. (Gambaud & Martens) *Consider an inverse limit sequence consisting of combinatorial covers $\{G_n\}_{n=1}^\infty$ and corresponding combinatorial refinements $\{\pi_n : G_{n+1} \rightarrow G_n\}_{n=1}^\infty$. The dynamical system (G, f) where the map*

Figure 4. An illustration of Example 1.18.

$f : G \rightarrow G$ is obtained by taking the inverse limit $G = \varprojlim_{\pi_n} G_n$ is a minimal Cantor set if and only if for every $n \in \mathbb{N}$ there exists an $m \in \mathbb{N}$ such that all entries in the first column of the matrix obtained from the product $W_n \dots W_m$ are at least 2.

Example 1.18. Consider a sequence of combinatorial covers $\{G_n\}_{n=1}^\infty$ where the combinatorial refinements $\pi_n : G_{n+1} \rightarrow G_n$ have identical corresponding winding matrices given by $W = \begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix}$ for each n . Since $W^3 = \begin{pmatrix} 3 & 2 \\ 2 & 1 \end{pmatrix}$, Theorem 1.17 guarantees that the map $f : G \rightarrow G$ obtained by taking the inverse limit $G = \varprojlim_{\pi_n} G_n$ is a minimal Cantor set.

Now suppose that in the above scenario the winding matrix W is given by $\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ instead. It can be shown that for any n , W^n is of the form $\begin{pmatrix} * & * \\ 0 & * \end{pmatrix}$. Because of the zero in the bottom left corner, Theorem 1.17 guarantees that the map $f : G \rightarrow G$ obtained by taking the inverse limit $G = \varprojlim_{\pi_n} G_n$ is not a minimal Cantor set.

1.3 Summary of Results

The study of a given dynamical system (X, f) is usually conducted from a perspective that “makes sense” for the space X and map f under consideration. If

X is a C^r -differentiable manifold and f is a C^r -diffeomorphism, the system can be approached from the point of view of differentiable dynamics. If X is a topological space and f is continuous, topological dynamics may be utilized. If X is a measure space and f measurable, the methods of measurable dynamics may be used.

In the case of a combinatorially obtained minimal Cantor set (X, f) , the space X is both a topological space and a measure space, and the map f is both continuous and measurable. The theory of topological dynamics and the theory of measurable dynamics both apply, and for this reason the topological and measure-theoretical properties of such a system are of great interest.

The remaining chapters of this work are concerned with exploring the measure-theoretical property of ergodicity and the construction of topological semi-conjugations in regards to combinatorially obtained minimal Cantor sets.

Definition 1.19. Given a probability space (X, Σ, μ) , a map $f : X \rightarrow X$ is called a *measure-preserving transformation* if f is measurable and $\mu(f^{-1}(A)) = \mu(A)$ for all $A \in \Sigma$. Furthermore, f is said to be *ergodic* if for every $A \in \Sigma$ with $f^{-1}(A) = A$ either $\mu(A) = 0$ or $\mu(A) = 1$. In this case the measure μ is called an *ergodic measure*.

Definition 1.20. Let X and Y be topological spaces and let $f : X \rightarrow X$ and $g : Y \rightarrow Y$ be continuous functions. The map f is said to be *topologically semi-conjugate* to the map g if there exists a continuous surjection $p : Y \rightarrow X$ such that $f \circ p = p \circ g$. The map p is called a *topological semi-conjugation*.

The study of ergodicity is important as ergodic theory allows us to come to a better understanding of how predictable an unpredictable dynamical system can be. Combinatorially obtained minimal Cantor sets are known to carry a set of ergodic invariant probability measures and non-uniquely ergodic minimal Cantor sets are known to exist. Both the paper of Gambaudo and Martens (see [4]) and

the 2011 doctoral thesis of Winckler (see [9]) contain examples of combinatorially obtained minimal Cantor sets that are not uniquely ergodic. In each of these examples, the authors rely upon winding matrices whose unbounded entries grow “fast enough” but do not address the necessary growth rate. Chapter 2 will provide details concerning these two examples before going on to establish the following main result on the growth rate needed to guarantee either unique or non-unique ergodicity for a specific family of combinatorially obtained minimal Cantor sets.

Theorem 2.7. *Let $a, b, m, p \in \mathbb{Z}^+$ be such that $a > b$ and $m \geq 2$. Then the minimal Cantor set corresponding to the sequences of $m \times m$ winding matrices $\{W_n\}_{n=1}^\infty$, with*

$$W_n = \begin{pmatrix} an^p & b & \dots & b \\ b & an^p & \ddots & \vdots \\ \vdots & \ddots & \ddots & b \\ b & \dots & b & an^p \end{pmatrix},$$

is uniquely ergodic when $p = 1$ and is not uniquely ergodic when $p > 1$. In the second case, there are in fact m ergodic invariant probability measures.

The remainder of Chapter 2 consists of theorems that establish the ergodicity of families of minimal Cantor sets that are combinatorially obtained from winding matrices with a similar structure to those that appear in Theorem 2.7. These results are then applied in the case of a specific type of map.

Chapters 3 and 4 use the results of Gambaudo and Martens to explore the construction of topological semi-conjugations between minimal Cantor sets, which is a topic of interest since such semi-conjugations are known to preserve a variety of dynamical properties. In Chapter 3, theorems guaranteeing the existence of a topological semi-conjugation between specific families of combinatorially obtained minimal Cantor sets will be established and utilized to prove the following main results.

Theorem 3.12. *The minimal Cantor set that is combinatorially obtained from the sequence of $m \times m$ ($m \geq 3$) winding matrices $\{W_n\}_{n=1}^\infty$, with*

$$W_n = \begin{pmatrix} a_n & a_n & a_n & \dots & a_n \\ na_n + 1 & (m-1)na_n & 2 & 2 & \dots & 2 \\ na_n + 1 & 2 & (m-1)na_n & 0 & \dots & 0 \\ na_n & 0 & 0 & \ddots & \ddots & \vdots \\ \vdots & & & \ddots & & 0 \\ na_n & 0 & \dots & 0 & (m-1)na_n \end{pmatrix},$$

is finitely non-uniquely ergodic for an appropriately chosen sequence of integers $\{a_n\}_{n=1}^\infty$. For such a sequence $\{a_n\}_{n=1}^\infty$, this minimal Cantor set can be semi-conjugated to a specific uniquely ergodic minimal Cantor set in such a way that the semi-conjugation map is almost everywhere injective with respect to the unique ergodic probability measure on the latter minimal Cantor set.

Theorem 3.18. *The minimal Cantor set that is combinatorially obtained from the sequence of $m_n \times (m_n + 1)$ ($m_n \geq 3$ and $m_n = n + 2$) winding matrices $\{W_n\}_{n=1}^\infty$, with*

$$W_n = \begin{pmatrix} a_n & a_n & \dots & a_n & a_n \\ \frac{1}{m_n-1}na_n + 1 & na_n & 2 & 2 & \dots & 2 & 2 \\ \frac{1}{m_n-1}na_n + 1 & 2 & na_n & 0 & \dots & 0 & 0 \\ \frac{1}{m_n-1}na_n & 0 & 0 & \ddots & \ddots & \vdots & \vdots \\ \vdots & \vdots & & \ddots & & 0 & 0 \\ \frac{1}{m_n-1}na_n & 0 & \dots & 0 & na_n & na_n \end{pmatrix}, \quad (1)$$

is infinitely non-uniquely ergodic for an appropriately chosen sequence of integers $\{a_n\}_{n=1}^\infty$. For such a sequence $\{a_n\}_{n=1}^\infty$, this minimal Cantor set can be semi-conjugated to a specific uniquely ergodic minimal Cantor set in such a way that the semi-conjugation map is almost everywhere injective with respect to the unique ergodic probability measure on the latter minimal Cantor set.

Finally, the main result of Chapter 4 proves that the non-uniquely ergodic minimal Cantor set of Theorem 3.12 can be taken to be $(\omega(c), q)$, where

$q : [0, 1] \rightarrow [0, 1]$ is a particular type of quadratic unimodal map with critical point c .

Theorem 4.24. *Given $m \geq 2$, there exists a quadratic map q with critical point c satisfying that $\omega(c)$ is a non-uniquely ergodic minimal Cantor set possessing m measures. Moreover, this quadratic maps satisfies that $(\omega(c), q)$ can be semi-conjugated to a specific uniquely ergodic minimal Cantor set in such a way that the semi-conjugation map is almost everywhere injective with respect to the unique ergodic probability measure on the latter minimal Cantor set.*

CHAPTER 2

Constructing Families of Ergodic Minimal Cantor Sets

2.1 Introduction

The number of ergodic invariant probability measures that a given combinatorially obtained minimal Cantor set carries can be investigated by using the winding matrices associated with it. A brief overview of the background involved in this process is outlined below; all details are provided by Gambaudo and Martens in [1].

Let (X, f) be a combinatorially obtained minimal Cantor set with inverse limit representation $X = \varprojlim_{\pi_n} X_n$ where each combinatorial cover X_n possesses d_n loops. Let $\mathcal{M}(X)$ be the space of signed invariant measures on (X, f) where Σ is the σ -algebra on X . The space of signed measures on X_n has σ -algebra Σ_n generated by the elements of X_n . Let U_1, \dots, U_{d_n} be the d_n images of the splitting vertex 0_{X_n} so that the loops of X_n are $\lambda(U_1), \dots, \lambda(U_{d_n})$. For $j = 1, \dots, d_n$, the loop $\lambda(U_j)$ carries an invariant measure $\nu_j^n : \Sigma_n \rightarrow \mathbb{R}$ with $\lambda(U_j)$ as support and $\nu_j^n(A) = 1$ if and only if $A \in \lambda(U_j)$.

Let $H_1(X_n)$ be the vector space generated by $\nu_1^n, \dots, \nu_{d_n}^n$. For a given measure $\mu \in \mathcal{M}(X)$, the inclusion $p_n : X \rightarrow X_n$ induces a map $(p_n)_* : \mathcal{M}(X) \rightarrow H_1(X_n)$ where $(p_n)_*(\mu)$ is the measure obtained when Σ is restricted to Σ_n . Similarly, the maps $\pi_n : X_{n+1} \rightarrow X_n$ induce a linear map $(\pi_n)_* : H_1(X_{n+1}) \rightarrow H_1(X_n)$. When represented using the bases $\{\nu_1^{n+1}, \dots, \nu_{d_{n+1}}^{n+1}\}$ and $\{\nu_1^n, \dots, \nu_{d_n}^n\}$, it can be shown that $(p_n)_* = W_n$, where W_n is the winding matrix corresponding to π_n . This result and the fact that $X = \varprojlim_{\pi_n} X_n$ leads to the conclusion that $\varprojlim_{W_n} H_1(X_n)$ is isomorphic to $\mathcal{M}(X)$.

Let $\mathcal{I}(X) \subset \mathcal{M}(X)$ be the set of invariant measures of f and let $\mathcal{P}(X) \subset \mathcal{I}(X)$

consist of the corresponding set of probability measures. Define

$$H_1^+(X_n) = \left\{ \sum_{j=1}^{d_n} \alpha_j \nu_j^n : \alpha_j \geq 0 \right\}.$$

Then $I(X_n) = \bigcap_{j=n+1}^{\infty} W_n \dots W_j (H_1^+(X_j))$ is the set of invariant measures associated with X_n and the corresponding set of probability measures is denoted by $P(X_n)$.

Note that each $I(X_n)$ is a cone in $H_1(X_n)$, $W_n(I(X_{n+1})) = I(X_n)$, and $\varprojlim_{W_n} I(X_n)$ is well-defined. Hence $\mathcal{I}(X)$ is isomorphic to $\varprojlim_{W_n} I(X_n)$ and $\mathcal{P}(X)$ is isomorphic to $\varprojlim_{W_n} P(X_n)$.

The proofs of Theorems 2.3 and 2.4 illustrate how this theory can be used to determine the number of ergodic probability measures carried by a given combinatorially obtained minimal Cantor set, and have been included below for this reason.

Definition 2.1. A minimal Cantor set is said to have *bounded combinatorics* if it can be combinatorially obtained in such a way that the entries of each winding matrix W_n are positive and the size and entries of these matrices are uniformly bounded.

Example 2.2. The minimal Cantor set obtained from the sequence of winding matrices $\{W_n\}_{n=1}^{\infty}$ where

$$W_n = \begin{pmatrix} 1 & 1 \\ 1 & 2^n \pmod{32} \end{pmatrix}$$

for each n is of bounded combinatorics since the largest entry that appears in any matrix is 16 and each matrix is 2×2 . However, the minimal Cantor set obtained from the sequence of winding matrices $\{W_n\}_{n=1}^{\infty}$ where

$$W_n = \begin{pmatrix} 1 & 1 \\ 1 & 2^n \end{pmatrix}$$

for each n is *not* of bounded combinatorics since matrix entries are unbounded (2^n approaches infinity as n approaches infinity).

Theorem 2.3. (Gambaud & Martens) *Let (X, f) where $X = \varprojlim_{\pi_n} X_n$ be a combinatorially obtained minimal Cantor set. If for each $n \in \mathbb{N}$ the number of loops in X_n is uniformly bounded by d then f has at most d ergodic invariant probability measures.*

Proof. Since the number of loops d_n in X_n is uniformly bounded by d for each n , we may assume without loss of generality that $d_n = d$ for each n . For $j = 1, \dots, d$, let t_j^n be the number of vertices in the loop $\lambda(U_j)$. The basis measures ν_1^n, \dots, ν_d^n of $H_1(X_n)$ may be normalized to probability measures μ_1^n, \dots, μ_d^n by setting $\mu_j^n = \frac{1}{t_j^n} \nu_j^n$ for $j = 1, \dots, d$.

Let $P_m(X_m) \subset H_1^+(X_m)$ be the set of probability measures and $P_n^m = W_{nm}(P_m)$. Since P_m is the convex hull of the $\{\mu_j^m\}$, P_n^m is the convex hull of the measures $\mu_j^{nm} = W_{nm}(\mu_j^m)$. By taking a subsequence it can be assumed that the measures μ_j^{nm} converge to measures $\mu_j \in P_n$ for $j = 1, \dots, d$. But $P(X_n) = \bigcap P_n^m$, so $P(X_n)$ is the convex hull of the measures $\{\mu_j : j = 1, \dots, d\}$ and therefore it is the convex hull of at most d points (and hence has at most d extreme points and, consequently, at most d ergodic measures).

For the sake of contradiction, suppose (X, f) carries more than d ergodic measures. For n sufficiently large, the projection of these ergodic measures would be distinct extremal points of $P(X_n)$, which has at most d extremal points. This contradiction yields the desired result. \square

Theorem 2.4. (Gambaud & Martens) *Let (X, f) be a combinatorially obtained minimal Cantor set. If (X, f) is of bounded combinatorics then (X, f) is uniquely ergodic.*

Proof. It suffices to show that $\mathcal{I}(X)$ is one-dimensional. To this end, note that

the hyperbolic distance between two points $x, y \in H_1^+(X_n)$ is

$$\text{hyp}(x, y) = -\ln \frac{(m + \ell)(m + r)}{\ell r}.$$

Here, m is the length of the line segment $[x, y]$ and ℓ, r are the length of the connected components of $T \setminus [x, y]$ where T is the largest line segment in $H_1^+(X_n)$ containing $[x, y]$. Positive matrices contract the hyperbolic distance on positive cones. Since X is of bounded combinatorics, the winding matrices W_n are uniformly bounded in size and entries. This implies that the contraction is uniform and

$$I(X_n) = \bigcap_{j=n+1}^{\infty} W_{j,n}(H_1^+(X_n))$$

is one-dimensional for each n . Since $\mathcal{I}(X)$ is isomorphic to $\lim_{W_n} I(X_n)$, it is also one dimensional. As $\mathcal{P}(X)$ is a subset of $\mathcal{I}(X)$, it is too one-dimensional and hence the map f has only one ergodic invariant probability measure. \square

2.2 Non-Uniquely Ergodic Minimal Cantor Sets

We are interested in constructing combinatorially obtained minimal Cantor sets that are either uniquely ergodic but not of bounded combinatorics or non-uniquely ergodic. In either case, Theorem 2.4 stipulates that this can only be done if the minimal Cantor set does not have bounded combinatorics; that is, the winding matrices W_n must be unbounded in size, possess unbounded entries, or both. To simplify computations, we will focus solely on those minimal Cantor sets that can be combinatorially obtained from square winding matrices of a fixed size. The next proposition, which is a consequence of Theorem 2.3, specifies the maximum number of ergodic invariant probability measures that such a combinatorially obtained minimal Cantor set can possess.

Proposition 2.5. *Let $m \in \mathbb{N}$ be fixed and let (X, f) be a minimal Cantor set that is combinatorially obtained from a sequence of winding matrices $\{W_n\}_{n=1}^{\infty}$ where each*

matrix is of size $m \times m$. Then (X, f) has at most m ergodic invariant probability measures.

Proof. Consider the corresponding inverse limit $X = \varprojlim_{\pi_n} X_n$ of f . For each n , the winding matrix W_n describes the projection from the combinatorial cover X_{n+1} to the combinatorial cover X_n . That is, for the images $\{V_j\}$ of the splitting vertex $0_{X_{n+1}}$ in X_{n+1} and the images $\{U_i\}$ of the splitting vertex 0_{X_n} in X_n , an entry $w_{ij} \in W_n$ is the number of times the loop $\lambda(V_j)$ of X_{n+1} passes through the loop $\lambda(U_i)$ of X_n . Since each W_n is an $m \times m$ matrix, each X_n must possess m loops. It is now clear that the number of loops in each X_n is uniformly bounded by m , and the result follows from Theorem 2.3. \square

Definition 2.6. A *Lorenz map* on $[0, 1] \setminus \{c\}$ is a monotone increasing differentiable map f on $[0, c) \cup (c, 1]$ with $f(0) = 0$ and $f(1) = 1$ and for which there exists a $c \in (0, 1)$ satisfying that $f'(x) \rightarrow 0$ as $x \rightarrow c$.

An illustration of a typical Lorenz map can be seen in Figure 5.

In [2], Winckler showed that there exist minimal Cantor sets under Lorenz maps which can be obtained from the sequence of winding matrices $\{W_n\}_{n=1}^\infty$, where

$$W_n = \begin{pmatrix} 1 & b_n \\ a_n & 1 \end{pmatrix} \quad (2)$$

and $\{a_n\}_{n=1}^\infty, \{b_n\}_{n=1}^\infty$ are unbounded sequences of integers. Winckler argued that when these unbounded sequences of integers grow quickly enough, it can be guaranteed that the corresponding minimal Cantor set will not be uniquely ergodic and will in fact possess two ergodic invariant probability measures. When these additional growth conditions are not met, the result is a uniquely ergodic minimal Cantor set that is not of bounded combinatorics.

Gambaud and Martens stated that there in fact exist minimal Cantor sets possessing $d - 1$ ergodic invariant probability measures which can be combinato-

Figure 5. Plot of a typical Lorenz map on $[0, 1] \setminus \{c\}$.

rially obtained from combinatorial covers X_n which all have $d > 1$ loops. Their construction requires the corresponding winding matrices W_n to consist of 1's everywhere except for specific entries along the main diagonal, where entries of the second and following columns consist of a large integer w_n . The result follows from choosing the sequence $\{w_n\}_{n=1}^{\infty}$ to be unbounded and growing sufficiently quickly.

Neither Winckler's Lorenz map example nor the example of Gambaudo and Martens provide insight into exactly how quickly the sequences of unbounded matrix entries must grow in order for non-unique ergodicity to be achieved. The main results in this section will introduce combinatorially obtained minimal Cantor sets whose associated winding matrices possess unbounded entries given by explicit sequences of integers. The specific structure of these winding matrices will allow us to address the precise growth rate needed to guarantee either unique or non-unique ergodicity given a specific additional restriction on the winding matrix entries of Winckler's Lorenz minimal Cantor set example.

Theorem 2.7. *Let $a, b, m, p \in \mathbb{Z}^+$ be such that $a > b$ and $m \geq 2$. Then the minimal Cantor set corresponding to the sequences of $m \times m$ winding matrices*

$\{W_n\}_{n=1}^\infty$, with

$$W_n = \begin{pmatrix} an^p & b & \dots & b \\ b & an^p & \ddots & \vdots \\ \vdots & \ddots & \ddots & b \\ b & \dots & b & an^p \end{pmatrix},$$

is uniquely ergodic when $p = 1$ and is not uniquely ergodic when $p > 1$. In the second case, there are in fact m ergodic invariant probability measures.

The proof of this result requires some knowledge regarding the convergence of infinite products.

Lemma 2.8. [3] *Let $\{a_n\}_{n=1}^\infty$ be a sequence of positive numbers. Then the infinite product $\prod_{n=1}^\infty (1 + a_n)$ converges if and only if the series $\sum_{n=1}^\infty a_n$ converges.*

Proof of Theorem 2.7. Consider a sequence of winding matrices $\{W_n\}_{n=1}^\infty$. As in [2], every invariant measure can be represented by an inverse limit of the sets

$$\{(z_1, z_2, \dots) : z_i = W_i z_{i+1}, z_i \in K\}$$

where $K \subset \mathbb{R}^m$ is the cone $\{(x_1, \dots, x_m) : x_i \geq 0\}$ and hence we should look on the sets

$$I_k = \bigcap_{n>k} W_k \dots W_{n-1} K.$$

We observe that if the limit as n approaches infinity of $W_k \dots W_n K$ is of dimension m for each k , it will follow that the minimal Cantor set corresponding to $\{W_n\}_{n=1}^\infty$ possesses m ergodic invariant probability measures. Similarly, if the limit as n approaches infinity of $W_k \dots W_n K$ is a one-dimensional space for each k , it will follow that the minimal Cantor set corresponding to $\{W_n\}_{n=1}^\infty$ is uniquely ergodic.

Let the main diagonal entries of the matrices W_n be given by an^p and all other entries are given by b . In seeking a convenient representation of the matrix

product $W_k \dots W_n$ for $n > k$, we observe that each W_n is symmetric and exhibits two distinct eigenvalues. The first, $\lambda_1^{(n)} = an^p - b$, is of multiplicity $m - 1$ and has corresponding eigenvectors v_i , where $i = 1, \dots, m - 1$, consisting of -1 in the first entry, 1 in the $(1 + m - i)$ -th entry, and zeros elsewhere. The second, $\lambda_2^{(n)} = an^p + b(m - 1)$, is of multiplicity one and has corresponding eigenvector consisting of all 1's. Hence each W_n has spectral decomposition PD_nP^{-1} , where

$$P = (v_1 \dots v_m) = \begin{pmatrix} -1 & -1 & \dots & -1 & -1 & 1 \\ 0 & 0 & \dots & 0 & 1 & 1 \\ 0 & \vdots & \ddots & 1 & 0 & 1 \\ \vdots & 0 & \ddots & \ddots & \vdots & \vdots \\ 0 & 1 & 0 & \dots & 0 & 1 \\ 1 & 0 & \dots & 0 & 0 & 1 \end{pmatrix} \quad (3)$$

and D_n is the diagonal matrix with entries $d_{ii}^{(n)} = \lambda_1^{(n)}$ for $i = 1, \dots, m - 1$ and $d_{mm}^{(n)} = \lambda_2^{(n)}$.

Now for $n > k$,

$$\begin{aligned} W_{kn} &= W_k \dots W_{n-1} W_n \\ &= (PD_kP^{-1}) \dots (PD_{n-1}P^{-1})(PD_nP^{-1}) \\ &= PDP^{-1} \end{aligned}$$

where $D = D_k \dots D_n$. The matrix D is diagonal with diagonal entries

$$d_{ii} = d_{11}^{(k)} \cdot \dots \cdot d_{11}^{(n)} = \prod_{\ell=k}^n (a\ell^p - b)$$

for $i = 1, \dots, m - 1$ and

$$d_{mm} = d_{mm}^{(k)} \cdot \dots \cdot d_{mm}^{(n)} = \prod_{\ell=k}^n (a\ell^p + b(m - 1)).$$

It can be shown that

$$\begin{aligned}
W_{kn} &= PDP^{-1} \\
&= \frac{d_{11}}{m} \begin{pmatrix} (m-1) + \frac{d_{mm}}{d_{11}} & \frac{d_{mm}}{d_{11}} - 1 & \dots & \frac{d_{mm}}{d_{11}} - 1 \\ \frac{d_{mm}}{d_{11}} - 1 & (m-1) + \frac{d_{mm}}{d_{11}} & & \frac{d_{mm}}{d_{11}} - 1 \\ \vdots & & \ddots & \vdots \\ \frac{d_{mm}}{d_{11}} - 1 & & & \frac{d_{mm}}{d_{11}} - 1 \\ \frac{d_{mm}}{d_{11}} - 1 & \dots & \frac{d_{mm}}{d_{11}} - 1 & (m-1) + \frac{d_{mm}}{d_{11}} \end{pmatrix}. \tag{4}
\end{aligned}$$

Let e_i be the vector consisting of all zeros except for a single 1 in the i -th position. The angle θ_n between $W_{kn}e_i$ and $W_{kn}e_j$ satisfies that

$$\cos \theta_n = \frac{W_{kn}e_i \cdot W_{kn}e_j}{\|W_{kn}e_i\| \|W_{kn}e_j\|}. \tag{5}$$

and

$$\theta_n = \arccos \left(\frac{W_{kn}e_i \cdot W_{kn}e_j}{\|W_{kn}e_i\| \|W_{kn}e_j\|} \right). \tag{6}$$

Thus the minimal Cantor set corresponding to $\{W_n\}_{n=1}^\infty$ is not uniquely ergodic if for each k there exist some e_i, e_j with $i \neq j$ where $\{\theta_n\}_{n=1}^\infty$ does not converge to zero as n approaches infinity. By equation (6), this is the same as showing that the righthand side of equation (5) does not converge to 1 as n approaches infinity. If no such e_i, e_j exist for each k , then the minimal Cantor set corresponding to $\{W_n\}_{n=1}^\infty$ is not uniquely ergodic.

We observe that for any $i \neq j$, equation (5) becomes

$$\cos \theta_n = \frac{2 \left((m-1) + \frac{d_{mm}}{d_{11}} \right) \left(\frac{d_{mm}}{d_{11}} - 1 \right) + (m-2) \left(\frac{d_{mm}}{d_{11}} - 1 \right)^2}{\left((m-1) + \frac{d_{mm}}{d_{11}} \right)^2 + (m-1) \left(\frac{d_{mm}}{d_{11}} - 1 \right)^2}. \tag{7}$$

Since the only term in the righthand side of equation (7) dependent upon n is

$$\frac{d_{mm}}{d_{11}} = \prod_{\ell=k}^n \frac{a\ell^p + b(m-1)}{a\ell^p - b} = \prod_{\ell=k}^n \left(1 + \frac{bm}{a\ell^p - b} \right), \quad (8)$$

the behavior of the righthand side of (7) as n approaches infinity depends upon the behavior of the product (8) as n approaches infinity. Note that $\frac{bm}{a\ell^p - b}$ is positive for each ℓ and hence by Lemma 2.8 the behavior of the product (8) as n approaches infinity can be determined by the behavior of the series

$$\sum_{\ell=k}^{\infty} \frac{bm}{a\ell^p - b}. \quad (9)$$

If $p = 1$, then series (9) diverges by comparison with the harmonic series $\sum_{\ell=k}^{\infty} \frac{1}{\ell}$. Hence the product (8) approaches infinity as n approaches infinity and it can be shown that the righthand side of equation (7) approaches 1 as n approaches infinity. Hence $\{\theta_n\}_{n=1}^{\infty}$ converges to 0 as n approaches infinity and it follows that the minimal Cantor set corresponding to the sequence of winding matrices $\{W_n\}_{n=1}^{\infty}$ is uniquely ergodic.

If $p > 1$, then series (9) converges by comparison with the p -series $\sum_{\ell=k}^{\infty} \frac{1}{\ell^p}$. Hence the product (8) converges to a nonnegative number, say T , as n approaches infinity and it can be shown that the righthand side of equation (7) converges to $\frac{T^2-1}{T^2-1+m}$ as n approaches infinity. This ratio is clearly never equal to 1 for any value of T , and so the righthand side of equation (7) does not converge to 1 as n approaches infinity. Hence $\{\theta_n\}_{n=1}^{\infty}$ does not converge to zero as n approaches infinity and it follows that the minimal Cantor set corresponding to the sequence of winding matrices $\{W_n\}_{n=1}^{\infty}$ is not uniquely ergodic. Moreover, since this result holds for any e_i, e_j where $1 \leq i, j \leq m$ and $i \neq j$, the corresponding minimal Cantor set in fact possesses m ergodic invariant probability measures. \square

The ergodicity of the above family of minimal Cantor sets was ultimately determined by a comparison test with a p -series. This result suggests that for

$\{w_n\}_{n=1}^\infty$ a sequence of integers that eventually grows faster than the sequence $\{n\}_{n=1}^\infty$, the minimal Cantor set that is combinatorially obtained from $m \times m$ ($m \geq 2$) winding matrices $\{W_n\}_{n=1}^\infty$ of the form

$$W_n = \begin{pmatrix} aw_n & b & \dots & b \\ b & aw_n & \ddots & \vdots \\ \vdots & \ddots & \ddots & b \\ b & \dots & b & aw_n \end{pmatrix}; \text{ where } a, b \in \mathbb{Z}^+ \text{ with } a > b$$

will not be uniquely ergodic. We will further explore this idea by introducing two additional families of non-uniquely ergodic minimal Cantor sets. As will be demonstrated, the ergodicity of the first is ultimately determined by a comparison test involving a geometric series.

Theorem 2.9. *Let $a, b, m \in \mathbb{Z}^+$ be such that $a > b$ and $m \geq 2$. Then the minimal Cantor set corresponding to the sequences of $m \times m$ winding matrices $\{W_n\}_{n=1}^\infty$, with*

$$W_n = \begin{pmatrix} a^n & b & \dots & b \\ b & a^n & \ddots & \vdots \\ \vdots & \ddots & \ddots & b \\ b & \dots & b & a^n \end{pmatrix}$$

is not uniquely ergodic. In fact, there are m ergodic invariant probability measures.

Note that the requirement that $a, b \in \mathbb{Z}^+$ with $a > b$ ensures that $a \neq 1$. If $a = 1$, then each W_n would be identical and the corresponding minimal Cantor set would be of bounded combinatorics, and hence uniquely ergodic by Theorem 2.4.

Proof of Theorem 2.9. We will utilize the method that was employed in the proof of Theorem 2.7.

Let the main diagonal entries of the matrices W_n be given by a^n and all other entries are given by b . Each W_n is symmetric and exhibits two distinct eigenvalues. The first, $\lambda_1^{(n)} = a^n - b$, is of multiplicity $m - 1$ and has corresponding eigenvectors

v_i , where $i = 1, \dots, m-1$ consisting of -1 in the first entry, 1 in the $(1+m-i)$ -th entry, and zeros elsewhere. The second, $\lambda_2^{(n)} = a^n + b(m-1)$, is of multiplicity one and has corresponding eigenvector consisting of all 1's. Hence each W_n has spectral decomposition PD_nP^{-1} , where P is the matrix given in (3) and D_n is the diagonal matrix with entries $d_{ii}^{(n)} = \lambda_1^{(n)}$ for $i = 1, \dots, m-1$ and $d_{mm}^{(n)} = \lambda_2^{(n)}$. Now for $k < n$, $W_{kn} = PDP^{-1}$ where $D = D_k \cdot \dots \cdot D_n$ is the diagonal matrix with diagonal entries

$$d_{ii} = d_{11}^{(k)} \cdot \dots \cdot d_{11}^{(n)} = \prod_{\ell=k}^n (a^\ell - b)$$

for $i = 1, \dots, m-1$ and

$$d_{mm} = d_{mm}^{(k)} \cdot \dots \cdot d_{mm}^{(n)} = \prod_{\ell=1}^n (a^\ell + b(m-1)).$$

The matrix product W_{kn} is given in equation (4).

Let e_i be the vector consisting of all zeros except for a single 1 in the i -th position. For $i \neq j$, the angle θ_n between $W_{kn}e_i$ and $W_{kn}e_j$ satisfies equations (5), (6), and (7) above, and it will follow that the minimal Cantor set corresponding to $\{W_n\}_{n=1}^\infty$ is not uniquely ergodic if it can be shown that there exist e_i, e_j with $i \neq j$ such that the sequence of angles $\{\theta_n\}_{n=1}^\infty$ does not converge to zero as n approaches infinity. This is equivalent to showing that the righthand side of equation (7) does not converge to 1 as n approaches infinity.

As above, the only term in the righthand side of equation (7) dependent upon n is

$$\frac{d_{mm}}{d_{11}} = \prod_{\ell=k}^n \frac{a^\ell + b(m-1)}{a^\ell - b} = \prod_{\ell=k}^n \left(1 + \frac{bm}{a^\ell - b} \right). \quad (10)$$

and $\frac{bm}{a^\ell - b}$ is positive for each ℓ . Hence by Lemma 2.8, the convergence of the product (10) depends on the convergence of the series $\sum_{\ell=k}^\infty \frac{bm}{a^\ell - b}$. This series converges by comparison with the geometric series $\sum_{\ell=k}^\infty \frac{1}{a^\ell}$ (to see this, recall that $a, b \in \mathbb{Z}^+$

with $a > b$, which implies that $a > 2$). Hence the righthand side of equation (10) converges to a nonnegative number, say T , as n approaches infinity and, as in the proof of Case 1 of Theorem 2.7, it can be shown that the righthand side of equation 7 converges to $\frac{T^2-1}{T^2-1+m}$ as n approaches infinity. Hence $\{\theta_n\}_{n=1}^\infty$ does not converge to zero as n approaches infinity and it follows that the minimal Cantor set corresponding to the sequence of winding matrices $\{W_n\}_{n=1}^\infty$ is not uniquely ergodic. Moreover, since this result holds for any e_i, e_j where $1 \leq i, j \leq m$ and $i \neq j$, the corresponding minimal Cantor set in fact possesses m ergodic invariant probability measures. \square

Theorem 2.10. *Let $a, b, m, p \in \mathbb{Z}^+$ be such that $a > b$ and $m \geq 2$. Then the minimal Cantor set corresponding to the sequences of $m \times m$ winding matrices $\{W_n\}_{n=1}^\infty$, with*

$$W_n = \begin{pmatrix} a^n n^p & b & \dots & b \\ b & a^n n^p & \ddots & \vdots \\ \vdots & \ddots & \ddots & b \\ b & \dots & b & a^n n^p \end{pmatrix}$$

is not uniquely ergodic. In fact, there are m ergodic invariant probability measures.

Proof. The proof is similar to the proofs of Theorems 2.7 and 2.9. \square

We wish to apply Theorems 2.7, 2.9, and 2.10 in the case of Lorenz minimal Cantor sets. However, each winding matrix that we have considered has unbounded entries located along the main diagonal while Lorenz minimal Cantor sets have winding matrices of form (2) with unbounded entries located along the minor diagonal. The subsequent theorem will allow us to overcome this obstacle.

Recall that a *permutation matrix* of size $m \times m$ can be obtained by permuting the rows of the $m \times m$ identity matrix. Left multiplication of a square matrix A

by a permutation matrix of the same size will permute the rows of A while right multiplication will permute the columns of A .

Theorem 2.11. *Let P be an $m \times m$ permutation matrix and let the sequence of matrices $\{W_n\}_{n=1}^\infty$ be defined as in one of Theorems 2.7, 2.9, or 2.10 . Then the ergodicity of the minimal Cantor set corresponding to the sequence of winding matrices $\{\widetilde{W}_n\}_{n=1}^\infty$, where*

$$\widetilde{W}_n = PW_n$$

for each n , is the same as the ergodicity of the minimal Cantor set corresponding to the sequence of winding matrices $\{W_n\}_{n=1}^\infty$.

To prove Theorem 2.11, we will make use of the following lemma from the theory of permutation matrices.

Lemma 2.12. [4] *An $m \times m$ matrix A commutes with every $m \times m$ permutation matrix if and only if*

$$A = \alpha I + \beta E,$$

where α, β are scalars, I is the $m \times m$ identity matrix, and E is the $m \times m$ matrix consisting of all 1's.

Proof of Theorem 2.11. Each matrix in the sequence of winding matrices $\{W_n\}_{n=1}^\infty$ defined as in one of Theorem 2.7, Theorem 2.9, or Theorem 2.10 can be written in the form $\alpha I + \beta E$ for some scalars α and β . Consequently, each W_n commutes with the permutation matrix P by Lemma 2.12.

We now proceed as in the proofs of Theorems 2.7 and 2.9. As before, let $\widetilde{W}_{kn} = \widetilde{W}_k \dots \widetilde{W}_n$. Since $\widetilde{W}_n = PW_n$ for each n , we have that

$$\begin{aligned} \widetilde{W}_{kn} &= PW_k \dots PW_n \\ &= P^{n-k} W_k \dots W_n \end{aligned}$$

by Lemma 2.12. The product $W_k \dots W_n$ is given in (4) and therefore

$$\widetilde{W}_{kn} = \frac{d_{11}}{m} P^{n-k} D$$

where D is the diagonal matrix

$$\begin{pmatrix} (m-1) + \frac{d_{mm}}{d_{11}} & \frac{d_{mm}}{d_{11}} - 1 & \dots & \frac{d_{mm}}{d_{11}} - 1 \\ \frac{d_{mm}}{d_{11}} - 1 & (m-1) + \frac{d_{mm}}{d_{11}} & & \frac{d_{mm}}{d_{11}} - 1 \\ \vdots & & \ddots & \vdots \\ \frac{d_{mm}}{d_{11}} - 1 & & & \frac{d_{mm}}{d_{11}} - 1 \\ \frac{d_{mm}}{d_{11}} - 1 & \dots & \frac{d_{mm}}{d_{11}} - 1 & (m-1) + \frac{d_{mm}}{d_{11}} \end{pmatrix}. \quad (11)$$

The d_{ii} depend upon the sequence $\{W_n\}_{n=1}^{\infty}$ in the following manner: if the sequence of winding matrices $\{W_n\}_{n=1}^{\infty}$ is defined as in Theorem 2.7, then the d_{ii} are defined as in Theorem 2.7. A similar result holds if the sequence of winding matrices $\{W_n\}_{n=1}^{\infty}$ is defined as in Theorem 2.9 or Theorem 2.10 instead.

As a power of a permutation matrix, P^{n-k} is itself a permutation matrix. Hence the product $\frac{d_{11}}{m} P^{n-k} D$ will be a scalar multiple of the matrix D with its rows permuted in some manner. Hence for each n , the angle θ_n between $\widetilde{W}_{kn} e_i$ and $\widetilde{W}_{kn} e_j$ for $i \neq j$ will satisfy equations (5), (6), and (7). As a consequence, the ergodicity of the minimal Cantor set corresponding to $\{\widetilde{W}_n\}_{n=1}^{\infty}$ must be the same as the ergodicity of the minimal Cantor set corresponding to the sequence of winding matrices $\{W_n\}_{n=1}^{\infty}$. \square

Example 2.13. Recall that there exist minimal Cantor sets under Lorenz maps that can be combinatorially obtained via the sequence of winding matrices $\{W_n\}_{n=1}^{\infty}$, where each W_n is defined as in equation (2). If we let $a_n = b_n$, the winding matrices satisfy that

$$W_n = \begin{pmatrix} 1 & a_n \\ a_n & 1 \end{pmatrix}.$$

Let P be the 2×2 permutation matrix with 1's along the minor diagonal so that

$$W_n = P \begin{pmatrix} a_n & 1 \\ 1 & a_n \end{pmatrix}.$$

Now for a and p integers satisfying that $a, p > 1$, Theorems 2.7, 2.9, 2.10 and 2.11 guarantee that the Lorenz minimal Cantor set corresponding to the sequence of winding matrices $\{W_n\}_{n=1}^\infty$ with

$$W_n = \begin{pmatrix} 1 & an \\ an & 1 \end{pmatrix}$$

is uniquely ergodic while the Lorenz minimal Cantor sets corresponding to the sequence of winding matrices $\{W_n\}_{n=1}^\infty$ with

$$W_n = \begin{pmatrix} 1 & an^p \\ an^p & 1 \end{pmatrix}, W_n = \begin{pmatrix} 1 & a^n \\ a^n & 1 \end{pmatrix}, \text{ or } W_n = \begin{pmatrix} 1 & a^n n^p \\ a^n n^p & 1 \end{pmatrix}$$

are not uniquely ergodic.

2.3 Future Work

The structure of each of the winding matrices considered in this chapter allowed for a convenient diagonal representation of the matrix product W_{kn} . This is not the case in general, as can be seen by considering the winding matrices introduced in the two conjectures below. These conjectures generalize the example of Gambaudo and Martens described below Proposition 2.5 and are supported by preliminary numerical trials. In each case, however, the eigenvectors corresponding to the winding matrix W_n depend upon n . This makes obtaining a closed form formula for the matrix product W_{kn} challenging, and it is likely that a different technique will need to be employed to establish the ergodicity of these and other minimal Cantor sets that are combinatorially obtained from winding matrices that exhibit less symmetry than those that were considered in Theorems 2.7, 2.9, 2.10, and 2.11.

Conjecture 2.14. Let $a, b, m, p \in \mathbb{Z}^+$ be such that $a > b$ and $m \geq 2$. Then the minimal Cantor set corresponding to the sequence of $m \times m$ winding matrices $\{W_n\}_{n=1}^\infty$, with

$$W_n = \begin{pmatrix} b & b & \dots & b \\ b & \ddots & & \\ & & b & \ddots & \vdots \\ \vdots & \ddots & an^p & & \\ & & & \ddots & b \\ b & \dots & b & an^p & \end{pmatrix} \text{ or } W_n = \begin{pmatrix} b & \dots & b & b \\ b & & \ddots & b \\ & & \ddots & b & \vdots \\ \vdots & an^p & \ddots & & \\ b & \ddots & & & \\ an^p & b & \dots & & b \end{pmatrix},$$

where there are $k \geq 2$ copies of an^p and $m - k$ copies of b along the main or minor diagonal, respectively, is uniquely ergodic when $p = 1$ and is not uniquely ergodic when $p > 1$. In the second case, there are in fact k ergodic invariant probability measures.

Conjecture 2.15. Let $a, b, m \in \mathbb{Z}^+$ be such that $a > b$ and $m \geq 2$. Then the minimal Cantor set corresponding to the sequence of $m \times m$ winding matrices $\{W_n\}_{n=1}^\infty$, with

$$W_n = \begin{pmatrix} b & b & \dots & b \\ b & \ddots & & \\ & & b & \ddots & \vdots \\ \vdots & \ddots & a^n & & \\ & & & \ddots & b \\ b & \dots & b & a^n & \end{pmatrix} \text{ or } W_n = \begin{pmatrix} b & \dots & b & b \\ b & & \ddots & b \\ & & \ddots & b & \vdots \\ \vdots & a^n & \ddots & & \\ b & \ddots & & & \\ a^n & b & \dots & & b \end{pmatrix},$$

where there are $k \geq 2$ copies of a^n and $m - k$ copies of b along the main or minor diagonal, respectively, is not uniquely ergodic and there are in fact k ergodic invariant probability measures.

CHAPTER 3

Almost Everywhere Injective Semi-Conjugations Between Certain Minimal Cantor Sets

3.1 Introduction

For $f : X \rightarrow X$ and $g : Y \rightarrow Y$ continuous functions, f is said to be *topologically conjugate* to g if there exists a homeomorphism $h : X \rightarrow Y$ such that $h \circ f = g \circ h$; that is, the following diagram commutes.

$$\begin{array}{ccc} X & \xleftarrow{f} & X \\ h \downarrow & & \downarrow h \\ Y & \xleftarrow{g} & Y \end{array}$$

Topological conjugacy plays an important role in studying the dynamics of continuous maps since two topologically conjugate maps are known to have the same dynamical properties.

Recall that for f and g defined as above, f is said to be *topologically semi-conjugate* to g if the function h above is a continuous, surjective function rather than a homeomorphism and the diagram is still commutative. In this case, the map h is called a *topological semi-conjugation*. Such semi-conjugations also preserve a number of dynamical properties, and if f is semi-conjugate to g , it can be said that the dynamics of (X, f) are at least as complicated as the dynamics of (Y, g) .

It is well-known that topological semi-conjugations do not preserve measure-theoretical properties. For this reason, it is not necessarily a surprising result that a non-uniquely ergodic minimal Cantor set may be semi-conjugated to a uniquely ergodic minimal Cantor set. In this chapter, it will be shown that for specific combinatorially obtained minimal Cantor sets, the above statement is true even

when the semi-conjugation map is almost everywhere injective with respect to the ergodic measure associated with the uniquely ergodic minimal Cantor set.

3.2 Semi-Conjugations Involving an Adding Machine

We will take as (Y, g) in the definition of a topological semi-conjugation a dynamical system chosen from a particular family of combinatorially obtained minimal Cantor sets called adding machines.

Definition 3.1. Let $\{w_n\}_{n=1}^\infty$ be a sequence of positive integers with $w_n \geq 2$ for each n . An *adding machine* is a minimal Cantor set that can be combinatorially obtained from a sequence of 1×1 winding matrices $\{W_n\}_{n=1}^\infty$ where $W_n = (w_n)$ for each n .

Note that adding machines are also frequently referred to as *solenoids* or *odometers* in the literature, where they have been studied by many authors, including Collas and Klein, Gambuado and Martens, and Oversteegen (see [1, 2, 3]).

Proposition 3.2. *An adding machine is uniquely ergodic.*

Proof. Since the dimension of each winding matrix is 1, the adding machine possesses at most one and hence exactly one ergodic invariant probability measure by Proposition 2.5. □

In sections 3.3 and 3.4, it will be shown that there exist topological semi-conjugations between non-uniquely ergodic combinatorially obtained minimal Cantor sets and adding machines that are almost everywhere injective with respect to the unique ergodic measure on the given adding machine. These results require the establishment of a property that will guarantee that certain combinatorially obtained minimal Cantor sets are topologically semi-conjugate to a given adding machine.

Proposition 3.3. *Let (X, f) with $X = \varprojlim_{\pi_n} X_n$ be a combinatorially obtained minimal Cantor set and let (Y, g) with $Y = \varprojlim_{\psi_n} Y_n$ be an adding machine. If each of the d_n loops of X_n possess the same number of vertices as the single loop of Y_n then for each $n \in \mathbb{Z}^+$ there exist continuous, surjective maps $p_n : X_n \rightarrow Y_n$ and $p_{n+1} : X_{n+1} \rightarrow Y_{n+1}$ such that $p_n \circ \pi_n = \psi_n \circ p_{n+1}$; that is, the following diagram commutes.*

$$\begin{array}{ccc}
 X_n & \xleftarrow{\pi_n} & X_{n+1} \\
 p_n \downarrow & & \downarrow p_{n+1} \\
 Y_n & \xleftarrow{\psi_n} & Y_{n+1}
 \end{array}$$

The proof of this proposition requires assigning “labels” to certain vertices in a given combinatorial cover.

Definition 3.4. Let (X, f) with $X = \varprojlim_{\pi_n} X_n$ be a combinatorially obtained minimal Cantor set. For a vertex x in a given loop of X_n , the *position of x in X_n* , denoted by $\ell_n(x)$, is the number of edges in the shortest directed path from the splitting vertex 0_{X_n} to x . The position of the splitting vertex 0_{X_n} in X_n is taken to be 0.

Note that if the combinatorially cover X_n is made up of multiple loops, there may be multiple vertices in a given position. To illustrate this, let U_1, \dots, U_{d_n} be the d_n distinct images of the splitting vertex 0_{X_n} . The shortest directed path from the splitting vertex to each of these vertices consists of a single directed edge, so each of U_1, \dots, U_{d_n} is said to be in position 1 in X_n .

Proof of Proposition 3.3. For each $n \in \mathbb{N}$, let t_n represent the number of vertices in the single loop of Y_n and let s_n represent in the number of vertices in each of the d_n loops of X_n . By hypothesis, $t_n = s_n$ for each $n \in \mathbb{N}$. Hence for each

$n \in \mathbb{N}$, there exists a continuous, surjective map $p_n : X_n \rightarrow Y_n$ that projects each loop of X_n once around the single loop of Y_n by mapping $x \in X_n$ to the unique vertex $y \in Y_n$ located in position $\ell_n(x)$ in Y_n . Specifically, this guarantees the existence of continuous, surjective maps $p_n : X_n \rightarrow Y_n$ and $p_{n+1} : X_{n+1} \rightarrow Y_{n+1}$ for each $n \in \mathbb{N}$.

It remains to be shown that for any $x \in X_{n+1}$, the equation

$$(p_n \circ \pi_n)(x) = (\psi_n \circ p_{n+1})(x)$$

holds. To prove this, fix $x \in X_{n+1}$. The position of x in X_{n+1} is $\ell_{n+1}(x)$. Now $\pi_n(x)$ is a vertex $x' \in X_n$ in position $\ell_{n+1}(x) \bmod s_n$. By definition, $p_n(x')$ is the unique vertex in Y_n that is in position $\ell_{n+1}(x) \bmod t_n$ since $s_n = t_n$ for each $n \in \mathbb{N}$.

Next consider $p_{n+1}(x)$. This will be the vertex $x'' \in Y_{n+1}$ that is in position $\ell_{n+1}(x)$ since $s_{n+1} = t_{n+1}$. Now $\psi_n(x'')$ is the unique vertex in Y_n that is in position $\ell_{n+1}(x) \bmod t_n$.

Since Y_n is a single loop, there can only be one vertex in position $\ell_{n+1}(x) \bmod t_n$. It follows that $(p_n \circ \pi_n)(x) = (\psi_n \circ p_{n+1})(x)$. \square

Theorem 3.5. *Let (X, f) and (Y, g) be as in Proposition 3.3. Then there exists a continuous, surjective map $p : X \rightarrow Y$ such that $f : X \rightarrow X$ and $g : Y \rightarrow Y$ satisfy that $p \circ f = g \circ p$; that is, the following diagram commutes.*

$$\begin{array}{ccc} X & \xleftarrow{f} & X \\ p \downarrow & & \downarrow p \\ Y & \xleftarrow{g} & Y \end{array}$$

Proof. Since Proposition 3.3 holds for each $n \in \mathbb{N}$, there exists a sequence $\{p_n\}$ of continuous, surjective maps $p_n : X_n \rightarrow Y_n$ satisfying that $p_n \circ \pi_n = \psi_n \circ p_{n+1}$.

This sequence extends to a continuous, surjective map $p : X \rightarrow Y$ satisfying that $p \circ f = g \circ p$. □

3.3 Semi-Conjugation Between a Finitely Non-Uniquely Ergodic Minimal Cantor Set and an Adding Machine

The main objective of this section is to show that there exists a family of finitely non-uniquely ergodic minimal Cantor sets that can be semi-conjugated to an adding machine in such a way that the semi-conjugation map is almost everywhere injective with respect to the uniquely ergodic probability measure associated with a corresponding adding machine. To do this, we will begin by establishing that the following family of combinatorially obtained minimal Cantor sets possesses members that are non-uniquely ergodic.

Proposition 3.6. *The minimal Cantor set that is combinatorially obtained from the sequence of winding matrices $\{W_n\}_{n=1}^\infty$, with*

$$W_n = \begin{pmatrix} a_n & a_n & a_n \\ na_n + 1 & 2na_n & 2 \\ na_n + 1 & 2 & 2na_n \end{pmatrix}$$

is not uniquely ergodic and in fact possesses at least two ergodic invariant probability measures for an appropriately chosen sequence of integers $\{a_n\}_{n=1}^\infty$.

Proof. Let

$$V = \{x \in \mathbb{R}^3 : x_1 = 0, x_2, x_3 \geq 0\}$$

and let e_1, e_2, e_3 be the standard basis vectors for \mathbb{R}^3 . The set of vectors $\{e_2, e_3\}$ forms a basis for V . For any two vectors $x, y \in V$, define

$$d(x, y) = \arccos \left(\frac{x \cdot y}{\|x\| \|y\|} \right); \tag{12}$$

that is, $d(x, y)$ gives the angle between the vectors x and y . Choose a_1 large enough so that

$$d(W_1 e_2, W_1 e_3) > \frac{\pi}{4} + \frac{1}{2},$$

a_2 large enough so that

$$d(W_1 W_2 e_2, W_1 W_2 e_3) > \frac{\pi}{4} + \frac{1}{3},$$

and, in general, choose a_n large enough so that

$$d(W_1 \dots W_n e_2, W_1 \dots W_n e_3) > \frac{\pi}{4} + \frac{1}{n+1}. \quad (13)$$

Since $W_k \dots W_n$ serves as a weaker contraction on V than $W_1 \dots W_n$ for $1 < k < n$, if it can be shown that

$$\lim_{n \rightarrow \infty} d(W_1 \dots W_n e_2, W_1 \dots W_n e_3) > 0,$$

it will follow that

$$\lim_{n \rightarrow \infty} d(W_k \dots W_n e_2, W_k \dots W_n e_3) > 0$$

for each $k < n$. This will prove that each of the sets $I_k = \bigcap_{n=k+1}^{\infty} W_k \dots W_n V$ is 2-dimensional, and so $\mathcal{I} = \lim_{\leftarrow} I_k$ is 2-dimensional, thus proving that the minimal Cantor set under consideration is not uniquely ergodic and in fact possesses at least two ergodic invariant probability measures. To this end, taking the limit as n approaches infinity of each side of inequality (13) results in

$$\lim_{n \rightarrow \infty} d(W_1 \dots W_n e_2, W_1 \dots W_n e_3) \geq \frac{\pi}{4}$$

and we have the desired result. □

The argument above can be generalized to the $m \times m$ case.

Proposition 3.7. *The minimal Cantor set that is combinatorially obtained from the sequence of $m \times m$ ($m \geq 3$) winding matrices $\{W_n\}_{n=1}^\infty$, with*

$$W_n = \begin{pmatrix} a_n & a_n & a_n & \cdots & a_n \\ na_n + 1 & (m-1)na_n & 2 & 2 & \cdots & 2 \\ na_n + 1 & 2 & (m-1)na_n & 0 & \cdots & 0 \\ na_n & 0 & 0 & \ddots & \ddots & \vdots \\ \vdots & & & \ddots & & 0 \\ na_n & 0 & \cdots & & 0 & (m-1)na_n \end{pmatrix}, \quad (14)$$

is not uniquely ergodic and in fact possesses at least $m - 1$ ergodic invariant probability measures for an appropriately chosen sequence of integers $\{a_n\}_{n=1}^\infty$.

Proof. The proof is analogous to the proof of Proposition 3.6. \square

For the remainder of this section, let (X, f) with $X = \varprojlim_{\pi_n} X_n$ be the minimal Cantor set that is combinatorially obtained as in Proposition 3.7. We will make the additional presumptions that each of the loops of X_n possesses the same number of vertices for each n and that any pair of loops in X_n has only the splitting vertex in common. Also, let (Y, g) with $Y = \varprojlim_{\psi_n} Y_n$ be an adding machine that is combinatorially obtained from the sequence of 1×1 winding matrices $\{((m-1)n+1)a_n+2\}_{n=1}^\infty$ and also satisfies that the single loop of Y_1 has the same number of vertices as each of the loops of the combinatorial cover X_1 .

Proposition 3.8. *For each $n \in \mathbb{N}$ there exist continuous, surjective maps*

$$p_n : X_n \rightarrow Y_n \text{ and } p_{n+1} : X_{n+1} \rightarrow Y_{n+1}$$

satisfying that $p_n \circ \pi_n = \psi_n \circ p_{n+1}$. Moreover, there exists a continuous, surjective map $p : X \rightarrow Y$ satisfying that $p \circ f = g \circ p$.

Proof. Let t_n be the number of vertices in Y_n and let s_n be the number of vertices in each loop of X_n for each $n \in \mathbb{N}$. Note that for each $n \in \mathbb{N}$, the number of

vertices t_{n+1} in the single loop of Y_{n+1} is given by

$$\left(((m-1)n+1)a_n + 2 \right) t_n$$

and the number of vertices s_{n+1} in each of the loops of X_{n+1} is given by the sum of the corresponding column of W_n . Since each of the columns of W_n sum to $((m-1)n+1)a_n + 2$, it follows that the number of vertices in each loop of X_{n+1} is given by

$$\left(((m-1)n+1)a_n + 2 \right) s_n.$$

Moreover, since $s_1 = t_1$, it follows that $s_n = t_n$ for each $n \in \mathbb{N}$. Hence the hypotheses of Proposition 3.3 and Theorem 3.5 are met and each of the results follows. \square

It remains to be shown that the semi-conjugation map p of Proposition 3.8 is almost everywhere injective with respect to the uniquely ergodic invariant probability measure associated with the adding machine (Y, g) .

For each $n \in \mathbb{N}$, recall that t_n represents the number of vertices in the single loop of Y_n . For each $n \in \mathbb{N} \setminus \{1\}$, define the set

$$\mathcal{U}_n = \left\{ y \in Y_n : \ell_n(y) \in \{0, 1, \dots, a_{n-1}t_{n-1}\} \right\}. \quad (15)$$

Note that \mathcal{U}_n consists of the first $a_{n-1}t_{n-1}$ vertices of the single loop of Y_n for each $n \in \{2, 3, \dots\}$.

Lemma 3.9. *Let $y = (y_1, \dots, y_n, y_{n+1}, \dots) \in Y$ satisfy that for some $n \in \mathbb{N}$, $y_{n+1} \in \mathcal{U}_{n+1}$ and suppose there exist*

$$x = (x_1, \dots, x_n, x_{n+1}, \dots), x' = (x'_1, \dots, x'_n, x'_{n+1}, \dots) \in X$$

such that $x, x' \in \{p^{-1}(y)\}$. Then $x_k = x'_k$ for $k = 1, \dots, n$.

Proof. Suppose $y_{n+1} \in \mathcal{U}_{n+1}$. Then $\ell_{n+1}(y_{n+1}) \in \{0, 1, \dots, a_n t_n\}$. We observe that $\#\{p_{n+1}^{-1}(y_{n+1})\}$ is either 1 or m since each of the m loops of X_{n+1} is projected once around the single loop of Y_{n+1} . Moreover, each of $x_{n+1}, x'_{n+1} \in \{p_{n+1}^{-1}(y_{n+1})\}$ is located in the same position (though possibly in distinct loops) in X_{n+1} as it is in Y_{n+1} since each of the loops of X_{n+1} are the same length as the single loop of Y_{n+1} .

Inspection of the winding matrix corresponding to π_n (see equation (14)) reveals that each loop of X_{n+1} is wrapped a_n times around the first loop of X_n . Since each loop of X_n is of length t_n , this means that each of the vertices located in a given position chosen from $0, 1, \dots, a_n t_n$ in X_{n+1} will be mapped to a single vertex in one of the positions $0, 1, \dots, t_n - 1$ in the first loop of X_n . In particular, $x_{n+1}, x'_{n+1} \in \{p_{n+1}^{-1}(y_{n+1})\}$ are mapped under π_n to a single vertex in X_n ; that is; $x_n = x'_n$. Now $x_k = x'_k$ for each $k = 1, \dots, n$ by the definition of an inverse limit. □

Proposition 3.10. *Let $y = (y_1, \dots, y_n, y_{n+1}, \dots) \in Y$ satisfy that $y_n \in \mathcal{U}_n$ for infinitely many $n \in \mathbb{N}$. Then $\#\{p^{-1}(y)\} = 1$.*

Proof. Let $x, x' \in \{p^{-1}(y)\}$. Since $y_n \in \mathcal{U}_n$ for infinitely many n , Lemma 3.9 yields that there exists an infinite sequence of positive integers $\{n_j\}_{j=1}^{\infty}$ satisfying that $n_1 < n_2 < \dots$ and $x_{k-1} = x'_{k-1}$ for $k = 1, \dots, n_j$. As an immediate consequence, $x = x'$. □

We will now show that the set of points $y = (y_1, \dots, y_n, \dots) \in Y$ satisfying that $y_n \in \mathcal{U}_n$ for infinitely many n (which, by Proposition 3.10, is exactly the set of points $y \in Y$ which have a unique pre-image under p) is of full measure with respect to the unique ergodic measure associated with the adding machine (Y, g) . This will complete the proof that the semi-conjugation map p is almost everywhere

injective with respect to this measure.

Proposition 3.11. *Let μ be the unique ergodic invariant probability measure associated with the adding machine (g, Y) , let \mathcal{U}_n be defined as in equation (15) of page 39, and let*

$$\mathcal{L}_0 = \{y \in Y : y_n \in \mathcal{U}_n \text{ for infinitely many values of } n\}.$$

Then $\mu(\mathcal{L}_0) = 1$.

Proof. Let

$$\mathcal{L}_1 = Y \setminus \mathcal{L}_0 = \{y \in Y : y_n \notin \mathcal{U}_n \text{ for all } n\}.$$

We will prove the equivalent statement that $\mu(\mathcal{L}_1) = 0$. To this end, let

$$L = \{0, \dots, t_1 - 1\} \times \dots \times \{0, \dots, t_n - 1\} \times \dots$$

where for each ℓ , the space $\{0, \dots, t_\ell - 1\}$ is equipped with the discrete topology. Note that we can associate to each $y = (y_1, \dots, y_n, \dots) \in Y$ the corresponding point $\ell_y = (\ell_1(y_1), \dots, \ell_n(y_n), \dots) \in L$ (and vice versa since Y_n consists of a single loop for each n). Hence there is a homeomorphism

$$H : Y \rightarrow L.$$

Now since Y_1 consists of t_1 vertices, Y_1 carries the probability measure which assigns to each vertex of Y_1 the weight $\frac{1}{t_1}$. For $n = 2, 3, \dots$, the combinatorial cover Y_n consists of $t_n = \left(((m-1)(n-1) + 1)a_{n-1} + 2 \right) t_{n-1}$ vertices, so Y_n carries the probability measure μ_n which assigns to each vertex of Y_n the weight

$$\frac{1}{\left(((m-1)(n-1) + 1)a_{n-1} + 2 \right) t_{n-1}}.$$

Hence L carries the product measure $\tilde{\mu}$ satisfying that $\tilde{\mu}(\ell_y) = \prod_{j=1}^{\infty} \mu_j(\ell_j(y_j))$.

For each $n \in \{2, 3, \dots\}$, the number of vertices in Y_n that are also in \mathcal{U}_n is $a_{n-1}t_{n-1}$. The number of vertices in Y_n that are *not* in \mathcal{U}_n is given by

$$t_n - a_{n-1}t_{n-1} = \left(((m-1)(n-1) + 1)a_{n-1} + 2 \right) t_{n-1} - a_{n-1}t_{n-1}.$$

Now

$$\begin{aligned} \tilde{\mu}(H(\mathcal{L}_1)) &= \frac{t_1}{t_1} \prod_{j=2}^{\infty} \frac{\left(((m-1)(j-1) + 1)a_{j-1} + 2 \right) t_{j-1} - a_{j-1}t_{j-1}}{\left(((m-1)(j-1) + 1)a_{j-1} + 2 \right) t_{j-1}} \\ &= \prod_{j=2}^{\infty} \left(1 - \frac{a_{j-1}}{\left((m-1)(j-1) + 1 \right) a_{j-1} + 2} \right). \end{aligned}$$

It can be shown that $\lim_{N \rightarrow \infty} \prod_{j=2}^N \left(1 - \frac{a_{j-1}}{\left((m-1)(j-1) + 1 \right) a_{j-1} + 2} \right) = 0$. The fact that $H : Y \rightarrow L$ is a homeomorphism and that Y is uniquely ergodic guarantees that $\mu(\mathcal{L}_1) = 0$, and we have the desired result. \square

Together, the results in this section prove the following theorem.

Theorem 3.12. *The minimal Cantor set that is combinatorially obtained from the sequence of $m \times m$ ($m \geq 3$) winding matrices $\{W_n\}_{n=1}^{\infty}$, with*

$$W_n = \begin{pmatrix} a_n & a_n & a_n & \dots & a_n \\ na_n + 1 & (m-1)na_n & 2 & 2 & \dots & 2 \\ na_n + 1 & 2 & (m-1)na_n & 0 & \dots & 0 \\ na_n & 0 & 0 & \ddots & \ddots & \vdots \\ \vdots & & & \ddots & & 0 \\ na_n & 0 & \dots & 0 & (m-1)na_n \end{pmatrix},$$

is finitely non-uniquely ergodic for an appropriately chosen sequence of integers $\{a_n\}_{n=1}^{\infty}$. For such a sequence $\{a_n\}_{n=1}^{\infty}$, this minimal Cantor set is semi-conjugated to an adding machine in such a way that the semi-conjugation map is almost everywhere injective with respect to the unique ergodic probability measure on the adding machine.

3.4 Semi-Conjugation Between an Infinitely Non-Uniquely Ergodic Minimal Cantor Set and an Adding Machine

The main result of the previous section shows that there exists a non-uniquely ergodic minimal Cantor set possessing any finite number of ergodic invariant probability measures we like that is semi-conjugated to an adding machine in such a way that the semi-conjugation is almost everywhere injective with respect to the unique ergodic measure associated with the adding machine. It seems natural that if this can be done with a non-uniquely ergodic minimal Cantor set carrying as many ergodic measures as we like, it should also be possible for a minimal Cantor set carrying an infinite number of ergodic measures. The main result of this section will show that this is indeed the case.

Thus far each of the constructions we have considered have consisted of minimal Cantor sets which can be combinatorially obtained from square winding matrices of the same size. Winding matrices are allowed to be rectangular, however, provided that the size of each winding matrix W_n leads to the matrix product $W_{kn} = W_k \dots W_n$ being well-defined for each $k < n$. In order to introduce an infinitely non-uniquely ergodic minimal Cantor set, we will consider a particular family of minimal Cantor set that can be combinatorially obtained from certain rectangular winding matrices.

Proposition 3.13. *For each n , let the W_n be given by the $m_n \times (m_n + 1)$ rectangular matrix*

$$W_n = \begin{pmatrix} a_n & a_n & \dots & a_n & a_n \\ \frac{1}{m_n-1}na_n + 1 & na_n & 2 & 2 & \dots & 2 & 2 \\ \frac{1}{m_n-1}na_n + 1 & 2 & na_n & 0 & \dots & 0 & 0 \\ \frac{1}{m_n-1}na_n & 0 & 0 & \ddots & \ddots & \vdots & \vdots \\ \vdots & \vdots & & \ddots & & 0 & 0 \\ \frac{1}{m_n-1}na_n & 0 & \dots & & 0 & na_n & na_n \end{pmatrix}, \quad (16)$$

where na_n is divisible by $m_n - 1$ and $m_n = n + 2$ for each n . For an appropriately

chosen sequence of integers $\{a_n\}_{n=1}^\infty$, the minimal Cantor set that is combinatorially obtained from the sequence of winding matrices $\{W_n\}_{n=1}^\infty$ is not uniquely ergodic and in fact possesses an infinite number of invariant probability measures.

Note that in the proposition above, W_1 is a 3×4 matrix, W_2 is a 4×5 matrix, W_3 is a 5×6 matrix, and so on. In particular, the matrix product $W_{kn} = W_k \dots W_n$ is well-defined for each $k < n$.

Proof of Proposition 3.13. For each n , let

$$V^{m_n} = \{x = (x_1, \dots, x_{m_n}) \in \mathbb{R}^{m_n} : x_1 = 0, x_2, \dots, x_{m_n} \geq 0\}$$

and let $e_1^{(m_n)}, \dots, e_{m_n}^{(m_n)}$ be the standard basis vectors for \mathbb{R}^{m_n} . The set of vectors $\{e_2^{(m_n)}, \dots, e_{m_n}^{(m_n)}\}$ forms a basis for V^{m_n} . For any two vectors $x, y \in V^{m_n}$, define $d : V^{m_n} \rightarrow \mathbb{R}$ to be the angle between the vectors x and y as in equation (12). As in Proposition 3.6, if it can be shown that for any $i \neq j$ with $i, j \neq 1$,

$$\lim_{n \rightarrow \infty} d(W_1 \dots W_n e_i^{(m_{n+1})}, W_1 \dots W_n e_j^{(m_{n+1})}) > 0,$$

it will follow that the minimal Cantor set under consideration is not uniquely ergodic. For each n , we may choose a_n large enough so that

$$d(W_1 \dots W_n e_i^{(m_{n+1})}, W_1 \dots W_n e_j^{(m_{n+1})}) > \frac{\pi}{4} + \frac{1}{n+1}.$$

By taking the limit as n approaches infinity of each side of the above inequality, it can be seen that

$$\lim_{n \rightarrow \infty} d(W_1 \dots W_n e_i^{(m_{n+1})}, W_1 \dots W_n e_j^{(m_{n+1})}) \geq \frac{\pi}{4}.$$

Since this holds for any $i \neq j$ with $i, j \neq 1$, it follows that the set

$$I_k = \bigcap_{n=k+1}^{\infty} W_k \dots W_n V^{m_{n+1}}$$

is at least $(m_k - 1)$ -dimensional for each k . As $\{m_k\}$ is a strictly increasing sequence of positive integers, $\mathcal{I} = \varprojlim_{W_n} I_k$ must be infinite-dimensional. Hence the minimal Cantor set that is combinatorially obtained from the sequence of winding matrices $\{W_n\}_{n=1}^\infty$ is not only non-uniquely ergodic, but in fact possesses an infinite number of ergodic invariant probability measures. \square

For the remainder of this section, let (X, f) with $X = \varprojlim_{\pi_n} X_n$ be the minimal Cantor set that is combinatorially obtained as in Proposition 3.13 and let (Y, g) with $Y = \varprojlim_{\psi_n} Y_n$ be an adding machine where each single loop Y_n has the same number of vertices t_n as each of the loops in X_n ; that is, (Y, g) is obtained combinatorially from the sequence of winding matrices $\{w_n\}_{n=1}^\infty$ where $w_n = ((n+1)a_n + 2)$ for each n , and X_1 and Y_1 are both assumed to have t_1 vertices. We also make the additional presumption that any pair of loops in X_n has only the splitting vertex in common.

Lemma 3.14. *For each $n \in \mathbb{N}$ there exist continuous, surjective maps $p_n : X_n \rightarrow Y_n$ and $p_{n+1} : X_{n+1} \rightarrow Y_{n+1}$ satisfying that $p_n \circ \pi_n = \psi_n \circ p_{n+1}$. Moreover, there exists a continuous, surjective map $p : X \rightarrow Y$ such that $p \circ f = g \circ p$.*

Proof. For each n , each of the loops of X_n has the same number of vertices as the single loop of Y_n . Since neither Proposition 3.3 nor Theorem 3.5 specify that the winding matrices corresponding to the minimal Cantor set where $X = \varprojlim_{\pi_n} X_n$ must be square, both findings hold regardless of the size of these winding matrices, and we have the desired result. \square

As in equation (15) of page 39, let

$$\mathcal{U}_n = \{y \in Y_n : \ell_n(y) \in \{0, 1, \dots, a_{n-1}t_{n-1}\}\}.$$

Lemma 3.15. *Let $y = (y_1, y_2, \dots, y_n, y_{n+1}, \dots) \in Y$ satisfy that for some n , $y_{n+1} \in \mathcal{U}_{n+1}$ and suppose there exist*

$$x = (x_1, \dots, x_n, x_{n+1}, \dots), x' = (x'_1, \dots, x'_n, x'_{n+1}, \dots) \in X$$

such that $x, x' \in \{p^{-1}(y)\}$. Then $x_k = x'_k$ for $k = 1, \dots, n$.

Proof. Note that the number of loops in X_{n+1} is given by the number of columns in W_n ; since W_n is an $m_n \times (m_n + 1)$ matrix, this number is $m_n + 1$.

Suppose $y_{n+1} \in \mathcal{U}_{n+1}$. Then $\ell_{n+1}(y_{n+1}) \in \{0, 1, \dots, a_n t_n\}$. We observe that $\#\{p_{n+1}^{-1}(y_{n+1})\}$ is either 1 or $m_n + 1$ since each of the $m_n + 1$ loops of X_{n+1} is projected once around the single loop of Y_{n+1} . Moreover, each of

$$x_{n+1}, x'_{n+1} \in \{p_{n+1}^{-1}(y_{n+1})\}$$

is located in the same position (though possibly in distinct loops) in X_{n+1} as it is in Y_{n+1} since each of the loops of X_{n+1} are the same length as the single loop of Y_{n+1} .

The remainder of the proof is identical to the second paragraph of the proof of Lemma 3.9. □

Proposition 3.16. *Let $y = (y_1, y_2, \dots, y_n, y_{n+1}, \dots) \in Y$ satisfy that $y_n \in \mathcal{U}_n$ for infinitely many n . Then $\#\{p^{-1}(y)\} = 1$.*

Proof. This is a consequence of Lemma 3.15. The proof is analogous to that of Proposition 3.10. □

We will now show that p is almost everywhere injective with respect to the uniquely ergodic invariant probability measure associated with the adding machine (Y, g) .

Proposition 3.17. *Let μ be the uniquely ergodic invariant probability measure associated with the adding machine (Y, g) and let*

$$\mathcal{L}_0 = \{y \in Y : y_n \in \mathcal{U}_n \text{ for infinitely many values of } n\}.$$

Then $\mu(\mathcal{L}_0) = 1$.

Proof. As in the proof of Proposition 3.11, we will let

$$\mathcal{L}_1 = Y \setminus \mathcal{L}_0 = \{y \in Y : y_n \notin \mathcal{U}_n \text{ for all } n\}.$$

and prove the equivalent statement that $\mu(\mathcal{L}_1) = 0$. Again, there exists a homeomorphism $H : Y \rightarrow L$ that assigns to each $y = (y_1, \dots, y_n, \dots) \in Y$ the corresponding point $\ell_y = (\ell_1(y_1), \dots, \ell_n(y_n), \dots) \in L$, where

$$L = \{0, \dots, t_1 - 1\} \times \dots \times \{0, \dots, t_n - 1\} \times \dots$$

Now Y_1 carries the probability measure which assigns to each vertex of Y_1 the weight $\frac{1}{t_1}$. For $n = 2, 3, \dots$, the combinatorial cover Y_n consists of $t_n = (na_{n-1} + 2)t_{n-1}$ vertices, so Y_n carries the probability measure μ_n which assigns to each vertex of Y_n the weight

$$\frac{1}{(na_{n-1} + 2)t_{n-1}}.$$

Hence L carries the product measure $\tilde{\mu}$ satisfying that $\tilde{\mu}(\ell_y) = \prod_{j=1}^{\infty} \mu_j(\ell_j(y_j))$.

The number of vertices in Y_n that are *not* in U_n for each n is given by

$$t_n - a_{n-1}t_{n-1} = (na_{n-1} + 2)t_{n-1} - a_{n-1}t_{n-1}.$$

Now

$$\begin{aligned} \tilde{\mu}(H(\mathcal{L}_1)) &= \frac{t_1}{t_1} \prod_{j=2}^{\infty} \frac{(ja_{j-1} + 2)t_{j-1} - a_{j-1}t_{j-1}}{(ja_{j-1} + 2)t_{j-1}} \\ &= \prod_{j=2}^{\infty} \left(1 - \frac{a_{j-1}}{ja_{j-1} + 2}\right). \end{aligned}$$

It can be shown that $\lim_{N \rightarrow \infty} \prod_{j=2}^N \left(1 - \frac{a_{j-1}}{ja_{j-1} + 2}\right) = 0$. The homeomorphism $H : Y \rightarrow L$ and the fact that Y is uniquely ergodic guarantees that $\mu(\mathcal{L}_1) = 0$, and we have the desired result. \square

We have proved the following theorem.

Theorem 3.18. *The minimal Cantor set that is combinatorially obtained from the sequence of $m_n \times (m_n + 1)$ ($m_n \geq 3$ and $m_n = n + 2$) winding matrices $\{W_n\}_{n=1}^\infty$, with*

$$W_n = \begin{pmatrix} a_n & a_n & \dots & a_n & a_n \\ \frac{1}{m_n-1}na_n + 1 & na_n & 2 & 2 & \dots & 2 & 2 \\ \frac{1}{m_n-1}na_n + 1 & 2 & na_n & 0 & \dots & 0 & 0 \\ \frac{1}{m_n-1}na_n & 0 & 0 & \ddots & \ddots & \vdots & \vdots \\ \vdots & \vdots & & \ddots & & 0 & 0 \\ \frac{1}{m_n-1}na_n & 0 & \dots & & 0 & na_n & na_n \end{pmatrix}, \quad (17)$$

is infinitely non-uniquely ergodic for an appropriately chosen sequence of integers $\{a_n\}_{n=1}^\infty$. For such a sequence $\{a_n\}_{n=1}^\infty$, this minimal Cantor set is semi-conjugated to an adding machine in such a way that the semi-conjugation map is almost everywhere injective with respect to the unique ergodic probability measure on the adding machine.

CHAPTER 4

Realization Under a Unimodal Map

4.1 Introduction

While the results of Chapter 3 are mathematically interesting in their own right, it is only natural to ask if the non-uniquely ergodic minimal Cantor set of Theorem 3.12 can be realized in a setting more familiar to the dynamical systems community. The main result of this chapter will show that this minimal Cantor set can in fact be taken to be $(\omega(c), q)$, where $q : [0, 1] \rightarrow [0, 1]$ is a logistic unimodal map with critical point c and $\omega(c)$ is the omega-limit set of this critical point.

4.2 Kneading Theory and Consequences for Unimodal Maps

Recall that a *unimodal map* is a map $u : [0, 1] \rightarrow [0, 1]$ satisfying $u(0) = u(1) = 0$ and for which there exists a *critical point* $c \in (0, 1)$ such that u is increasing to the left of c and decreasing to the right of c .

One family of unimodal maps that we will consider is a subset of the family of *tent maps* as defined in Example 1.2. We will consider those maps $T_a : [0, 1] \rightarrow [0, 1]$ where

$$T_a(x) = \begin{cases} ax, & x \leq \frac{1}{2} \\ a(1-x), & x \geq \frac{1}{2} \end{cases}$$

and $a \in (0, 2]$. Note that each tent map achieves its maximum value at its critical point $x = \frac{1}{2}$.

Closely related to the family of tent maps is the family of *stunted tent maps*, which consist of those functions $\mathcal{S}_{a,p} : [0, 1] \rightarrow [0, 1]$ for which the corresponding tent map T_a has been “stunted” by replacing its peak with a plateau at a given height $p \in (0, 1)$ on a closed, symmetric interval of positive length about $x = \frac{1}{2}$ (see Figure 6). In the case of stunted tent maps, the critical point is taken by

Figure 6. Plots of the tent map T_2 and a corresponding stunted tent map $\mathcal{S}_{2,p}$.

convention to be $x = \frac{1}{2}$.

Another important family of unimodal maps is the family of *logistic maps* consisting of those functions $q_a : [0, 1] \rightarrow [0, 1]$ defined by $q_a(x) = ax(1 - x)$ where $a \in (0, 4]$ (see Figure 7). Note that in the case of logistic maps, the maximum value occurs at its critical point $x = \frac{1}{2}$ as well.

For a given unimodal map u with critical point c , the *itinerary* of a point $x \in [0, 1]$ under u is given by

$$I(x) = s_0 s_1 \dots \text{ with } s_i = \begin{cases} 0 & \text{if } u^i(x) \leq c \\ 1 & \text{if } u^i(x) > c \end{cases}.$$

Note that if $u^i(x) = c$, we take s_i to be 0 without loss of generality. The *kneading sequence* K of a unimodal map is the given by the itinerary of the critical value $u(c) = c_1$; that is, $K = I(c_1)$. Moreover, a binary sequence $s \in \{0, 1\}^{\mathbb{N}}$ is said to be *admissible* for u if there exists $x \in [0, 1]$ with itinerary $I(x) = s$.

Kneading sequences and kneading theory were introduced and explored by Milnor and Thurston in their paper *On Iterated Maps of the Interval* (see [1]).

Figure 7. Plot of the logistic unimodal map $q_4(x) = 4x(1 - x)$.

We will use the related theory developed by Isola and Politi (see [2]) in order to determine whether or not a given binary sequence $s \in \{0, 1\}^{\mathbb{N}}$ is admissible as the kneading sequence of a smooth unimodal map.

Let $\sigma : \{0, 1\}^{\mathbb{N}} \rightarrow \{0, 1\}^{\mathbb{N}}$ be the left shift map defined by

$$\sigma(s_0 s_1 \dots) = s_1 s_2 \dots$$

Then for a unimodal map u and $x \in [0, 1]$, the itinerary $I(x) = s_0 s_1 s_2 \dots$ satisfies that

$$I(u(x)) = s_1 s_2 \dots = \sigma(I(x)).$$

Once an ordering that reflects the ordering on the real line has been established, it is known that the admissible binary sequences are exactly those which never become greater than the kneading sequence when shifted.

The method of Isola and Politi begins by associating to a given sequence $s = s_1 s_2 \dots \in \{0, 1\}^{\mathbb{N}}$ a number $\tau(s) \in [0, 1]$ defined by

$$\tau = 0.t_1 t_2 \dots = \sum_{k \geq 1} t_k 2^{-k}, \text{ where } t_k = \sum_{i=1}^k s_i \pmod{2}.$$

Let $\sigma : \{0, 1\}^{\mathbb{N}} \rightarrow \{0, 1\}^{\mathbb{N}}$ be the left shift map, let $T : [0, 1] \rightarrow [0, 1]$ be the tent map defined by

$$T(x) = \begin{cases} 2x, & x \leq \frac{1}{2} \\ 2(1-x), & x \geq \frac{1}{2} \end{cases},$$

and let $u : [0, 1] \rightarrow [0, 1]$ be a smooth unimodal map with critical point c and critical value $c_1 = u(c)$. Direct verification confirms that the following diagram commutes.

$$\begin{array}{ccccc} [0, 1] & \xrightarrow{I} & \{0, 1\}^{\mathbb{N}} & \xrightarrow{\tau} & [0, 1] \\ u \downarrow & & \downarrow \sigma & & \downarrow T \\ [0, 1] & \xrightarrow{I} & \{0, 1\}^{\mathbb{N}} & \xrightarrow{\tau} & [0, 1] \end{array}$$

Since c_1 is the maximum value in the image of u and it can be proved that the map $\tau \circ I$ is increasing (see [3]), the next theorem holds.

Theorem 4.1. (Isola & Politi) *Let $T : [0, 1] \rightarrow [0, 1]$ be the tent map defined by*

$$T(x) = \begin{cases} 2x, & x \leq \frac{1}{2} \\ 2(1-x), & x \geq \frac{1}{2} \end{cases}$$

A binary sequence $s \in \{0, 1\}^{\mathbb{N}}$ is the kneading sequence of a smooth unimodal map if and only if $\tau := \tau(s)$ satisfies

$$T^k(\tau) \leq \tau \text{ for all } k \geq 0.$$

The following result allows the smooth unimodal map of Theorem 4.1 to be taken to be a logistic map.

Theorem 4.2. (Milnor & Thurston) *Any binary sequence which is admissible as the kneading sequence of a unimodal map can be realized as the kneading sequence of a logistic unimodal map.*

Also related to the kneading sequence of a unimodal map u is the *kneading map*.

Definition 4.3. Let J be a maximal interval on which $u^n|_J$ is monotone. Then $u^n : J \rightarrow u^n(J)$ is called a *branch*. If $c \in \partial J$ (i.e., c is an endpoint of J), then $u^n : J \rightarrow u^n(J)$ is called a *central branch*. If the image of a central branch of u^n contains c , then n is called a *cutting time*. The cutting times are denoted by S_0, S_1, S_2, \dots

Definition 4.4. For each $k \in \mathbb{N}$, the difference between two consecutive cutting times S_k and S_{k-1} is also a cutting time and the *kneading map* is defined as

$$Q(k) := S_k - S_{k-1}.$$

Example 4.5. The Feigenbaum unimodal map exhibits cutting times given by powers of 2; that is, $S_0 = 1$ and $S_k = 2S_{k-1}$ for $k \in \mathbb{N}$. Hence its kneading map is given by

$$\begin{aligned} Q(k) &= S_k - S_{k-1} \\ &= 2S_{k-1} - S_{k-1} \\ &= S_{k-1} \end{aligned}$$

so that $Q(k) = 2(k - 1)$.

Example 4.6. The Fibonacci unimodal map is named after its cutting times, which are given by the Fibonacci numbers; that is; $S_0 = 1$, $S_1 = 1$, and $S_k = S_{k-1} + S_{k-2}$ for $k \in \{2, 3, \dots\}$. Hence its kneading map is given by

$$\begin{aligned} Q(k) &= S_k - S_{k-1} \\ &= S_{k-1} + S_{k-2} - S_{k-1} \\ &= S_{k-2} \end{aligned}$$

so that $Q(k) = \max\{k - 2, 0\}$.

Remark 4.7. It is known that two unimodal maps with the same kneading sequence have the same kneading map, and vice versa.

The proof of the following result can be found in [4].

Theorem 4.8. (Cortez & Rivera-Letelier) *Let u be a smooth unimodal map with critical point c satisfying that $(\omega(c), u)$ is a minimal Cantor set. If \tilde{u} is a unimodal map having the same kneading map as u , then $(\omega(\tilde{c}), \tilde{u})$ is also a minimal Cantor set and the space of invariant probability measures of \tilde{u} supported on $\omega(\tilde{c})$ is homeomorphic to that of u .*

In particular, the above states that the number of ergodic measures of u supported on $\omega(c)$ is the same as those of \tilde{u} supported on $\omega(\tilde{c})$.

4.3 Obtaining the Desired Unimodal Map

This section will culminate in the main result proving the existence of a logistic unimodal map q for which $(\omega(c), q)$ is non-uniquely ergodic and may be semi-conjugated to an adding machine in such a way that the semi-conjugation map is almost everywhere injective.

To prove this result, we will begin by showing that there exists a minimal Cantor set under the tent map T of Theorem 4.1 that is homeomorphic to a non-uniquely ergodic combinatorially obtained minimal Cantor set satisfying the hypotheses of Theorem 3.12.

Remark 4.9. By taking $m = 3$ in Theorem 3.12, it can be said that the minimal Cantor set (X, f) with $X = \varprojlim_{\pi_n} X_n$ that is combinatorially obtained from the sequence of winding matrices $\{W_n\}_{n=1}^{\infty}$, where

$$W_n = \begin{pmatrix} a_n & a_n & a_n \\ na_n + 1 & 2na_n & 2 \\ na_n + 1 & 2 & 2na_n \end{pmatrix},$$

is non-uniquely ergodic for an appropriately chosen sequence of integers $\{a_n\}_{n=1}^\infty$. For such a sequence $\{a_n\}_{n=1}^\infty$, this minimal Cantor set is semi-conjugated to the adding machine (Y, g) with $Y = \varprojlim_{\psi_n} Y_n$ satisfying that, for each n , the single loop Y_n has the same number of vertices t_n as each of the three loops in X_n . Moreover, the semi-conjugation map p is almost everywhere injective with respect to the unique ergodic probability measure μ on (Y, g) .

Definition 4.10. Given a finite set of elements \mathcal{W} , a *word* ω of length N in \mathcal{W} is given by $\omega = \omega_1 \dots \omega_N$ where ω_i is a single element of \mathcal{W} for each $i \in \{1, \dots, N\}$. The set of all such words is denoted by \mathcal{W}^N .

Lemma 4.11. Fix $N \in \{2, 3, \dots\}$. Let $I_0, I_1,$ and I_2 be compact, pairwise disjoint subsets of $[0, 1]$ and suppose that $\mathfrak{o} : [0, 1] \rightarrow [0, 1]$ is a continuous, piecewise strictly monotone map with monotone and onto branches $\mathfrak{o}_k : I_k \rightarrow [0, 1]$ for $k = 0, 1, 2$ (see Figure 8). Then for all words $\omega = \omega_1 \omega_2 \dots \omega_{N-1} \in \{0, 1, 2\}^{N-1}$ there exists a unique, compact interval $I^\omega \subset I_0$ such that

1. $\mathfrak{o}^\ell(I^\omega) \subseteq I_{\omega_\ell}$ for $\ell = 1, \dots, N-1$ with equality only in the case when $\ell = N-1$.
2. $\mathfrak{o}^N : I^\omega \rightarrow [0, 1]$ is monotone and onto.

Proof. The proof is by induction on N . For the base case, let $N = 2$. Then $\omega = \omega_1$ where $\omega_1 \in \{0, 1, 2\}$. Since $\mathfrak{o}_0(I_0) = [0, 1]$, there exists a unique, compact interval given by $\mathfrak{o}_0^{-1}(I_k) \subset I_0$ for each $k \in \{0, 1, 2\}$. Set $I^{\omega_1} = \mathfrak{o}_0^{-1}(I_{\omega_1})$. Then $\mathfrak{o}(I^{\omega_1}) = I_{\omega_1}$. Moreover, $\mathfrak{o}^2 : I^{\omega_1} \rightarrow [0, 1]$ is monotone and onto. Monotonicity follows from the fact that $\mathfrak{o}|_{I_0}$ is monotone and surjectivity follows from the fact that $\mathfrak{o}^2(I^{\omega_1}) = [0, 1]$.

For the induction hypothesis, suppose that for each word

$$\tilde{\omega} = \omega_1 \dots \omega_{N-1} \in \{0, 1, 2\}^{N-1},$$

Figure 8. A possible configuration of the intervals I_k and the branches $\mathfrak{o}_k : I_k \rightarrow [0, 1]$ ($k = 0, 1, 2$) of the map \mathfrak{o} as described in Lemma 4.11.

there exists a unique, compact interval $I^{\tilde{\omega}} \subset I_0$ such that

1. $\mathfrak{o}^\ell(I^{\tilde{\omega}}) \subseteq I_{\omega_\ell}$ for $\ell = 1, \dots, N - 1$ with equality only in the case when $\ell = N - 1$.
2. $\mathfrak{o}^N : I^{\tilde{\omega}} \rightarrow [0, 1]$ is monotone and onto.

We will show that the result holds for each word $\omega \in \{0, 1, 2\}^N$. For such a word, $\omega = \tilde{\omega}\omega_N$ where $\tilde{\omega} \in \{0, 1, 2\}^{N-1}$. Set $I^\omega = (\mathfrak{o}^N|_{I^{\tilde{\omega}}})^{-1}(I_{\omega_N})$. Then $I^\omega \subset I^{\tilde{\omega}} \subset I_0$ and $\mathfrak{o}^\ell(I^\omega) \subset I_{\omega_\ell}$ for $\ell = 1, \dots, N - 1$ by the induction hypothesis. Moreover, $\mathfrak{o}^N(I^\omega) = I_{\omega_N}$ by direct computation. Finally, $\mathfrak{o}^{N+1} : I^\omega \rightarrow [0, 1]$ is monotone and onto since $\mathfrak{o} \circ \mathfrak{o}^N|_{I^\omega}$ is monotone and $\mathfrak{o}^{N+1}(I^\omega) = [0, 1]$. \square

Lemma 4.12. *Fix $N \in \{2, 3, \dots\}$ and let $\omega, \omega' \in \{0, 1, 2\}^{N-1}$. Let I_0, I_1, I_2 , $\mathfrak{o} : [0, 1] \rightarrow [0, 1]$, and $\mathfrak{o}_k : I_k \rightarrow [0, 1]$ for $k = 0, 1, 2$ be as in Lemma 4.11. Suppose that I_0 satisfies that $\mathfrak{o}^\ell(\partial I_0) \cap \text{int}(I_0) = \emptyset$ for all $\ell \in \mathbb{N}$ and let $I^\omega, I^{\omega'} \subset I_0$ be pairwise distinct intervals satisfying that $\mathfrak{o}^{N-1}(I^\omega) = \mathfrak{o}^{N-1}(I^{\omega'}) = I_0$ (note that this can be done by Lemma 4.11). Then*

$$\mathfrak{o}^{\ell_1}(I^\omega) \cap \mathfrak{o}^{\ell_2}(I^{\omega'}) \neq \emptyset \text{ for some } \ell_1 \leq \ell_2 \in \mathbb{N} \implies \mathfrak{o}^{\ell_1}(I^\omega) = \mathfrak{o}^{\ell_2}(I^{\omega'}).$$

Proof. For the sake of contradiction, suppose that $\mathfrak{o}^{\ell_1}(I^\omega) \cap \mathfrak{o}^{\ell_2}(I^{\omega'}) \neq \emptyset$ and that $\mathfrak{o}^{\ell_1}(I^\omega) \neq \mathfrak{o}^{\ell_2}(I^{\omega'})$. Then there are three possibilities: either $\mathfrak{o}^{\ell_2}(I^{\omega'}) \subset \text{int}(\mathfrak{o}^{\ell_1}(I^\omega))$, $\partial\mathfrak{o}^{\ell_1}(I^\omega) \cap \text{int}(\mathfrak{o}^{\ell_2}(I^{\omega'})) \neq \emptyset$, or $\mathfrak{o}^{\ell_1}(I^\omega)$ and $\mathfrak{o}^{\ell_2}(I^{\omega'})$ intersect at a common endpoint only.

Case 1: Suppose $\mathfrak{o}^{\ell_2}(I^{\omega'}) \subset \text{int}(\mathfrak{o}^{\ell_1}(I^\omega))$. Then

$$I_0 = \mathfrak{o}^{N-1-\ell_2}(\mathfrak{o}^{\ell_2}(I^{\omega'})) \subset \mathfrak{o}^{N-1-\ell_2}(\mathfrak{o}^{\ell_1}(I^\omega)) \subset I_k$$

for some $k \in \{0, 1, 2\}$, an immediate contradiction.

Case 2: If $\partial\mathfrak{o}^{\ell_1}(I^\omega) \cap \text{int}(\mathfrak{o}^{\ell_2}(I^{\omega'})) \neq \emptyset$, then there exists an endpoint d of $\mathfrak{o}^{\ell_1}(I^\omega)$ that also lies in the interior of $\mathfrak{o}^{\ell_2}(I^{\omega'})$. Since d is an endpoint of $\mathfrak{o}^{\ell_1}(I^\omega)$, $d' = \mathfrak{o}^{N-1-\ell_1}(d)$ is an endpoint of I_0 by monotonicity. Since d is also an element of the interior of $\mathfrak{o}^{\ell_2}(I^{\omega'})$, $d' = \mathfrak{o}^{N-1-\ell_2}(d)$ as well and is in the interior of $\mathfrak{o}^{N-1-\ell_2}(\text{int}(\mathfrak{o}^{\ell_1}(I^\omega)))$. Hence $\mathfrak{o}^{\ell_2-\ell_1}(d')$ must be in the interior of I_0 . Now an iterate of d' , which is itself an endpoint of I_0 , intersects the interior of I_0 . This contradicts the assumption that $\mathfrak{o}^\ell(\partial I_0) \cap \text{int}(I_0) = \emptyset$ for all $\ell \in \mathbb{N}$.

Case 3: If $\mathfrak{o}^{\ell_1}(I^\omega)$ and $\mathfrak{o}^{\ell_2}(I^{\omega'})$ intersect only at a common endpoint, monotonicity implies that not both $\mathfrak{o}^{N-1-\ell_1}(\mathfrak{o}^{\ell_1}(I^\omega))$, $\mathfrak{o}^{N-1-\ell_2}(\mathfrak{o}^{\ell_2}(I^{\omega'}))$ can be I_0 , a contradiction. \square

For the remainder of this section, let (X, f) with $X = \varprojlim_{\pi_n} X_n$ and (Y, g) with $Y = \varprojlim_{\psi_n} Y_n$ be the minimal Cantor sets defined as in Remark 4.9. Then t_n is the number of vertices in the single loop of Y_n as well as the number of vertices in each loop of X_n . Inspection of the sequence of winding matrices associated with the sequence of combinatorial covers $\{\pi_n\}_{n=1}^\infty$ given in Remark 4.9 reveals that $t_{n+1} = ((2n+1)a_n + 2)t_n$ for each $n \in \mathbb{N}$.

Let $T : [0, 1] \rightarrow [0, 1]$ be the tent map defined in Theorem 4.1 and suppose that for each $n \in \mathbb{N} \cup \{0\}$, some iterate of T is monotone and onto on each of three

compact, pairwise disjoint intervals I_0^n, I_1^n, I_2^n (note that this can be done as T is a piecewise monotone map). Lemma 4.11 implies that there exist unique, pairwise disjoint intervals $I_0^{n+1}, I_1^{n+1}, I_2^{n+1} \subset I_0^n$ satisfying that

- $I_0^{n+1} \mapsto T(I_0^{n+1}) \mapsto \dots \mapsto T^{t_n-1}(I_0^{n+1}) \mapsto T^{t_n-1}(I_0^{n+1}) = I_0^n$
- $I_1^{n+1} \mapsto T(I_1^{n+1}) \mapsto \dots \mapsto T^{t_n-1}(I_1^{n+1}) \mapsto T^{t_n-1}(I_0^{n+1}) = I_0^n$
- $I_2^{n+1} \mapsto T(I_2^{n+1}) \mapsto \dots \mapsto T^{t_n-1}(I_2^{n+1}) \mapsto T^{t_n-1}(I_0^{n+1}) = I_0^n$

and $T^\ell(I_k^{n+1})$ is a proper subset of one of I_0^n, I_1^n, I_2^n for $\ell = 1, \dots, t_n - 1$ and $k \in \{0, 1, 2\}$. Lemma 4.12 additionally allows us to presume that if $T^{\ell_1}(I_{k_1}^n) \cap T^{\ell_2}(I_{k_2}^n) \neq \emptyset$, then $T^{\ell_1}(I_{k_1}^n) = T^{\ell_2}(I_{k_2}^n)$. Moreover, Lemma 4.11 results in a natural inclusion of the orbit of I_k^{n+1} for each k within the orbits of I_j^n for $j = 0, 1, 2$. We can specifically assume that this inclusion reflects the winding matrices $\{W_n\}_{n=1}^\infty$ as defined in Remark 4.9.

For each $n \in \mathbb{N}$ and $k \in \{0, 1, 2\}$, the intervals I_k^{n+1} are pairwise disjoint with orbits under T that come to coincide at some iterate t , where $1 \leq t \leq t_n - 1$. The orbits of these intervals can thus be thought of in the sense of a combinatorial cover, as will be explained in detail within the proof of the next proposition.

Proposition 4.13. *For each $n \in \mathbb{N}$ and each $k \in \{0, 1, 2\}$ define*

$$\mathcal{O}_n = \left\{ \bigcup_{k=0}^2 T^t(I_k^n) : 0 \leq t \leq t_n - 1 \right\}.$$

Then there exists a combinatorial cover $X_n^\mathcal{O}$ and a homeomorphism $h_n : \mathcal{O}_n \rightarrow X_n^\mathcal{O}$ for each $n \in \mathbb{N}$.

Proof. For each $k \in \{0, 1, 2\}$ and $n \in \mathbb{N}$, consider the subset of the orbit of I_k^n under the tent map T given by

$$\lambda(I_k^n) = \{I_k^n, T(I_k^n), \dots, T^{t_n-1}(I_k^n)\}.$$

By definition, $\lambda(I_k^n)$ consists of exactly t_n intervals for each k and n .

To form the combinatorial cover $X_n^\mathcal{O}$, begin by creating a vertex for each interval in $\lambda(I_0^n)$. Place a directed edge between two vertices x and y if and only if the interval $T^\ell(I_0^n)$ associated with the vertex x satisfies that $T^{\ell+1}(I_0^n)$ is the interval associated with the vertex y . Proceed in the same fashion with $\lambda(I_1^n)$ and $\lambda(I_2^n)$, but if any of the intervals in either of these is the same as an interval I in I_0^n , associate the interval with the same vertex that I was associated with. Note that this construction results in the vertex associated with I_0^{n-1} being the splitting vertex of $X_n^\mathcal{O}$ and the intervals $T(I_0^n)$, $T(I_1^n)$, and $T(I_2^n)$ corresponding to the vertices that are the images of this splitting vertex.

This construction of $X_n^\mathcal{O}$ results in a natural homeomorphism $h_n : \mathcal{O}_n \rightarrow X_n^\mathcal{O}$ for each n . □

As we wish to consider minimal Cantor sets, the next step is to prove that there also exists a sequence of combinatorial refinements $\{\pi_n^\mathcal{O} : X_{n+1}^\mathcal{O} \rightarrow X_n^\mathcal{O}\}_{n=1}^\infty$.

Proposition 4.14. *For each n , there exists a combinatorially refinement*

$$\pi_n^\mathcal{O} : X_{n+1}^\mathcal{O} \rightarrow X_n^\mathcal{O}$$

that can be described by the sequence of winding matrices associated with the combinatorial refinements $\pi_n : X_{n+1} \rightarrow X_n$.

Proof. For each $n \in \mathbb{N}$, $X_n^\mathcal{O}$ consists of three loops of length

$$t_n = ((2(n-1) + 1)a_{n-1} + 2)t_{n-1}.$$

Due to how the sets \mathcal{O}_n were chosen, a combinatorial refinement $\pi_n^\mathcal{O} : X_{n+1}^\mathcal{O} \rightarrow X_n^\mathcal{O}$ may be defined in such a way that the corresponding sequence of winding matrices is given by $\{W_n\}_{n=1}^\infty$ (the same sequence used to obtain the non-uniquely ergodic minimal Cantor set (X, f) of Remark 4.9). □

This sequence of combinatorial refinements together with the sequence of homeomorphisms from Proposition 4.13 allows us to project between the sets \mathcal{O}_n .

Proposition 4.15. *For each $n \in \mathbb{N}$, there exists a continuous, surjective map $\psi_n^\mathcal{O} : \mathcal{O}_{n+1} \rightarrow \mathcal{O}_n$ which may be described by the winding matrices $\{W_n\}_{n=1}^\infty$ of Remark 4.9.*

Proof. Lemmas 4.13 and 4.14 yield the following diagram.

$$\begin{array}{ccc} X_n^\mathcal{O} & \xleftarrow{\pi_n^\mathcal{O}} & X_{n+1}^\mathcal{O} \\ h_n^{-1} \downarrow & & \downarrow h_{n+1} \\ \mathcal{O}_n & & \mathcal{O}_{n+1} \end{array}$$

This diagram implies the existence of a continuous, surjective map $\psi_n^\mathcal{O} : \mathcal{O}_{n+1} \rightarrow \mathcal{O}_n$ given by $\psi_n^\mathcal{O} = h_n^{-1} \circ \pi_n^\mathcal{O} \circ h_{n+1}$ for each $n \in \mathbb{N}$ which may be described by the winding matrices $\{W_n\}_{n=1}^\infty$ associated with $\{\pi_n^\mathcal{O}\}_{n=1}^\infty$. \square

We now have two inverse limit sequences $\{X_n^\mathcal{O}, \pi_n^\mathcal{O}\}_{n=1}^\infty$ and $\{\mathcal{O}_n, \psi_n^\mathcal{O}\}_{n=1}^\infty$ and will show that each can be used to obtain a minimal Cantor set.

Proposition 4.16. *Let $(X^\mathcal{O}, f^\mathcal{O})$ be the minimal Cantor set combinatorially obtained from $X^\mathcal{O} = \varprojlim_{\pi_n^\mathcal{O}} X_n^\mathcal{O}$ and let $\mathcal{O} = \varprojlim_{\psi_n^\mathcal{O}} \mathcal{O}_n$. Then $X^\mathcal{O}$ is homeomorphic to \mathcal{O} . Moreover, (\mathcal{O}, T) is a minimal Cantor set that is topologically conjugate to $(X^\mathcal{O}, f^\mathcal{O})$.*

Proof. Since Lemmas 4.13 and 4.15 hold for each $n \in \mathbb{N}$, there exists a sequence $\{\tilde{h}_n : \mathcal{O}_n \rightarrow X_n^\mathcal{O}\}_{n=1}^\infty$ of homeomorphisms satisfying that $\tilde{h}_n \circ \pi_n^\mathcal{O} = \psi_n^\mathcal{O} \circ \tilde{h}_{n+1}$. This sequence extends to a homeomorphism $h : \mathcal{O} \rightarrow X^\mathcal{O}$. Now $h \circ f^\mathcal{O} = T \circ h$, since T is the map that describes the orbits of I_k^n for each n and hence also the orbits of \mathcal{O} . Now, \mathcal{O} is topologically conjugate to $X^\mathcal{O}$ and (\mathcal{O}, T) must also be a minimal Cantor set. \square

The above specifically proves that there exists a minimal Cantor set under the tent map T that is homeomorphic to the minimal Cantor set $(X^\mathcal{O}, f^\mathcal{O})$ which was combinatorially obtained in a similar fashion to the non-uniquely ergodic minimal Cantor set (X, f) of Remark 4.9. Since (X, f) is semi-conjugated to the adding machine (Y, g) of Remark 4.9, our next step is to show that $(X^\mathcal{O}, f^\mathcal{O})$ (and hence (\mathcal{O}, T)) can be semi-conjugated to (X, f) .

Proposition 4.17. *There exists a continuous, surjective map $p^\mathcal{O} : X \rightarrow X^\mathcal{O}$ satisfying that $p^\mathcal{O} \circ f = f^\mathcal{O} \circ p^\mathcal{O}$.*

Proof. Each of the three loops of the combinatorial cover X_n consists of t_n vertices with the only common vertex being the splitting vertex. Each of the three loops of the combinatorial cover $X_n^\mathcal{O}$ also consists of t_n vertices, but in this case each loop may have multiple vertices in common.

Let $U_1, U_2,$ and U_3 be the images of the splitting vertex in X_n and let $U_1^\mathcal{O}, U_2^\mathcal{O},$ and $U_3^\mathcal{O}$ be the images of the splitting vertex in $X_n^\mathcal{O}$. Define the $p_n^\mathcal{O} : X_n \rightarrow X_n^\mathcal{O}$ so that the vertex $x \in \lambda(U_i)$ that is located in position $\ell_n(x)$ in X_n is mapped to the vertex $y \in \lambda(U_i^\mathcal{O})$ located in position ℓ_n in $X_n^\mathcal{O}$. By definition, $p_n^\mathcal{O}$ is continuous and onto for each n and satisfies that $p_n^\mathcal{O} \circ \pi_n = \pi_n^\mathcal{O} \circ p_{n+1}^\mathcal{O}$.

The sequence of maps $\{p_n : X_n \rightarrow X_n^\mathcal{O}\}_{n=1}^\infty$ may then be extended to a continuous, surjective map $p^\mathcal{O} : X \rightarrow X^\mathcal{O}$ satisfying that $p^\mathcal{O} \circ f = f^\mathcal{O} \circ p^\mathcal{O}$. \square

Proposition 4.18. *There exists a continuous, surjective map $\rho : X^\mathcal{O} \rightarrow Y$ satisfying that $\rho \circ f^\mathcal{O} = g \circ \rho$.*

Proof. Since each of the loops of $X_n^\mathcal{O}$ has the same number of vertices as the single loop of Y_n for $n = 0, 1, \dots$, Theorem 3.5 guarantees the existence of a continuous, surjective map $\rho : X^\mathcal{O} \rightarrow Y$ with the desired property. \square

We have the following commutative diagram.

Now $(X^\mathcal{O}, f^\mathcal{O})$ (and hence (\mathcal{O}, T)) is semi-conjugated to the adding machine (Y, g) . It remains to be shown that ρ is in fact almost everywhere injective with respect to the unique ergodic invariant probability measure on (Y, g) .

Proposition 4.19. *The map $\rho : X^\mathcal{O} \rightarrow Y$ is almost everywhere injective with respect to the unique ergodic measure μ on (Y, g) .*

Proof. Since the diagram

commutes, $\{y \in Y : \#\rho^{-1}(y) \geq 2\} \subseteq \{y \in Y : \#p^{-1}(y) \geq 2\}$. Moreover, $\mu(\{y \in Y : \#p^{-1}(y) \geq 2\}) = 0$ as a consequence of Proposition 3.11, and hence $\mu(\{y \in Y : \#\rho^{-1}(y) \geq 2\}) = 0$ as well. \square

We have proved the following result.

Theorem 4.20. *There exists a non-uniquely ergodic minimal Cantor set under the tent map T of Theorem 4.1 that can be semi-conjugated to a specific adding machine in such a manner that the semi-conjugation map is almost everywhere injective with respect to the single ergodic invariant probability measure associated with the adding machine.*

This theorem brings us one step close to our ultimate goal of proving that the minimal Cantor set of Remark 4.9 can be taken to be $(\omega(c), q)$ for some logistic map q with critical point c . However, \mathcal{O} is *not* the omega limit set of the critical point of T . We can make it the omega limit set of the critical point of a particular corresponding stunted tent map, however. To this end, let ν be the maximal element of the Cantor set \mathcal{O} and let \mathcal{S} be the stunted tent map corresponding to T with plateau at height ν . Now $(\omega(\nu), \mathcal{S})$ is exactly the same as (\mathcal{O}, T) . Moreover, ν is the critical value of \mathcal{S} and we can consider the kneading sequence $K = I(\nu)$ of \mathcal{S} .

Proposition 4.21. *The binary sequence $K = I(\nu)$ is admissible as the kneading sequence of a logistic unimodal map.*

Proof. The tent map T and the stunted tent map \mathcal{S} agree on \mathcal{O} . Since ν is the maximal element of the Cantor set \mathcal{O} and T maps \mathcal{O} to itself, $T^k(\nu) \leq \nu$ for all $k \in \mathbb{N} \cup \{0\}$. It immediately follows from Theorem 4.1 and Theorem 4.2 that there exists a quadratic unimodal map q with kneading sequence given by K . \square

Proposition 4.22. *Let $q : [0, 1] \rightarrow [0, 1]$ be the logistic unimodal map whose existence was guaranteed by Proposition 4.21. The minimal Cantor set $(\omega(c), q)$ is non-uniquely ergodic.*

Proof. Since two unimodal maps with the same kneading invariant also have the same kneading map (see Remark 4.7), it follows immediately from Theorem 4.8 and the previous results in this section that $(\omega(c), q)$ is non-uniquely ergodic. \square

Together, the results of this section prove the subsequent result.

Theorem 4.23. *There exists a logistic unimodal map with critical point c satisfying that $\omega(c)$ is a non-uniquely ergodic minimal Cantor set that can be semi-conjugated to a specific adding machine in such a manner that the semi-conjugation*

map is almost everywhere injective with respect to the single ergodic invariant probability measure associated with the adding machine.

Even though we chose to consider the simplest possible sequence of winding matrices from Theorem 3.12, the lemmas, propositions, and proofs within this section can be easily modified to prove the result when considering any sequence of winding matrices that matches the criteria laid out in the statement of Theorem 3.12. This results in the following more general theorem.

Theorem 4.24. *Given $m \geq 2$, there exists a logistic unimodal map q with critical point c satisfying that $\omega(c)$ is a non-uniquely ergodic minimal Cantor set possessing m measures. Moreover, this logistic map satisfies that $(\omega(c), q)$ can be semi-conjugated to a specific adding machine in such a way that the semi-conjugation map is almost everywhere injective with respect to the single ergodic invariant probability measure associated with the adding machine.*

4.4 Future Work

In this chapter, we proved that there exist finitely non-uniquely ergodic minimal Cantor sets obtained as the omega-limit set of certain logistic unimodal maps that may be semi-conjugated to a corresponding adding machine in such a way that the semi-conjugation map is almost everywhere injective with respect to the unique ergodic measure on the adding machine. It is likely that the lemmas, propositions, and proofs contained within this chapter can be modified in order to prove the same result where the logistic map is infinitely non-uniquely ergodic instead.

Conjecture 4.25. There exists a logistic unimodal map q with critical point c satisfying that $(\omega(c), q)$ is an infinitely non-uniquely ergodic minimal Cantor that can be semi-conjugated to a specific adding machine in such a way that the semi-conjugation map is almost everywhere injective with respect to the single ergodic

invariant probability measure associated with the adding machine.
