Abstract

Effective interventions require an understanding of the behaviors and cognitions that facilitate positive change as well as the development of psychometrically sound measures. This paper reports on the psychometric properties of the Temptations to Try Alcohol Scale (TTAS), including factorial invariance across different subgroups. Data were collected from 3565 6th grade RI middle school students. Structural equation modeling was used to determine the appropriate factorial invariance model for the 9-item TTAS. The measure consists of three correlated subscales: Social Pressure, Social Anxiety, and Opportunity. Three levels of invariance, ranging from the least to the most restrictive, were examined: Configural Invariance, which constrains only the factor structure and zero loadings; Pattern Identity Invariance, which requires factor loadings to be equal across the groups; and Strong Factorial Invariance, which requires factor loadings and error variances to be constrained. Separate analyses evaluated the invariance across two levels of gender (males vs. females), race (white vs. black) ethnicity (Hispanic vs. Non-Hispanic) and school size (small, meaning <200 6th graders, or large). The highest level of invariance, strong factorial invariance, provided a good fit to the model for gender (CFI: .95), race (CFI: .94), ethnicity (CFI: .94), and school size (CFI: .97). Coefficient Alpha was .90 for Social Pressure, .81 for Social Anxiety, and .82 for Opportunity. These results provide strong empirical support for the psychometric structure and construct validity of the TTAS in middle school students.

Keywords

Factorial Invariance; Self-efficacy; Situational Temptations; Transtheoretical Model; Alcohol Prevention

Rates of alcohol use increase throughout middle school years, despite serious negative consequences. To effectively intervene on the problem of alcohol use, measures must be developed that assess behaviors and cognitions relevant to the problem. The transtheoretical
model of behavior change (TTM; Prochaska & Velicer, 1997; Velicer et al., 2000) is an integrative framework made up of multiple dimensions. The TTM has been validated in many studies and has been used to develop many effective, population-based interventions (Velicer et al., 2000). The core constructs of TTM include stages of change, processes of change, decisional balance, and self-efficacy (or situational temptations). The Situational Temptations Scale assesses an individual’s desire to perform a behavior in difficult situations (Velicer, DiClemente, Rossi, & Prochaska, 1990) and is based on the self-efficacy construct of Bandura (1977; 1982) and the relapse prevention literature. This paper describes a variation of the measure, designed for the prevention of alcohol acquisition with middle school students. Based on preliminary results (Burditt, Harrington, Redding, Velicer, Paiva, Meier, Oatley, & Prochaska, 2009), the Temptations to Try Alcohol Scale (TTAS) is a correlated three-factor model with nine items; three items each for Social Pressure, Social Anxiety, and Opportunity. The measure is currently being used in a computerized multi-media alcohol prevention program which delivers interactive interventions tailored to each student’s particular risk profile. To be a useful part of the intervention, the TTAS must be reliable and valid; the goal of this paper is to assess the psychometric properties of the scale, including factorial invariance.

Factorial invariance is critical to establishing psychometric properties of any measure. It determines whether the set of items assesses the same theoretical constructs across different subgroups (Meredith & Teresi, 2006). This paper reports on the factorial invariance across subgroups defined by gender, ethnicity, race, and school size. This scale has been previously validated among high school students and more recently, in a large sample of middle school students (Burditt et al., 2009). In this paper different levels of factorial invariance are examined in a sequential order with increasingly constrained models to assess the equivalence of the Temptations to Try Alcohol Scale across different subsamples.

The first level of invariance examined was Configural Invariance, also called weak factorial invariance, which is an unconstrained model for the non-zero loadings and assumes the same number of factors and same items associated with each factor are found across subpopulations (Meredith, 1993; Meredith & Teresi, 2006). Configural invariance is a prerequisite for testing any more constrained measurement invariance models. The second level of invariance, Pattern Identity Invariance, requires that factor loadings are invariant across groups. The highest level, Strong Factorial Invariance, requires invariant factors and error variances. Meaningful group comparisons can be assumed when strong factorial invariance is observed (Meredith, 1993; Meredith & Teresi, 2006). Coefficient Alphas for each subgroup was also calculated to assess scale reliability.

**Method**

**Participants**

Data used in this paper were collected from 3565 6th grade Rhode Island middle school students from 20 schools. The data comes from an ongoing study that delivers computerized a multi-media alcohol and tobacco prevention program based on TTM framework. The sample was 82% white and 48% female.

**Procedure**

Structural equation modeling was used to determine the most appropriate factorial invariant model for the 9-item Temptations to Try Alcohol Scale. Three levels of invariance, ranging from the least to the most restrictive were examined. This paper evaluated the invariance across two levels of gender (male, n = 1827 and female, n = 1709), race (White, n = 2346 and Black = 98) ethnicity (Hispanic, n = 3005 and Non-Hispanic, n = 479) and school size.
Temptations to Try Alcohol Scale

The Temptations to Try Alcohol Scale consists of three correlated subscales: Social Pressure, Social Anxiety, and Opportunity (see Figure 1). The sequential method of scale development (Jackson, 1971) was used to create the measure. It has been previously evaluated among high school students and more recently, in a sample of middle school students (Burditt et al., 2009).

Factorial invariance

All levels of invariance: configural invariance, pattern identity invariance, and strong factorial invariance were assessed using the following indices: comparative fit index (CFI), normed fit index (NFI), nonnormed fit index (NNFI), and root mean square error of approximation (RMSEA). Values of at least .90 are considered acceptable and values greater than .95 are preferable (Bentler, 1990) for CFI, NFI and NNFI. For RMSEA, values less than .08 are acceptable and below .05 are preferable (Hu & Bentler, 1999). In addition, a CFI difference between a model and the level of invariance below it was calculated to determine whether a null hypothesis of invariance should be rejected. A value of −0.01 or less indicates measurement invariance (Cheung & Rensvold, 2002).

Results

Factorial invariance of Temptations to Try Alcohol Scale

Structural equation modeling (SEM) performed with EQS software (Bentler, 2004) was used to examine hierarchical factorial invariance (See Table 1 for detailed results).

Gender

Strong factorial invariance provided a good fit for the model, with n = 1837 for males and n = 1714 for females (CFI = .951; NFI = .948; NNFI = .939; RMSEA = .109).

Ethnicity

Strong factorial invariance provided a good fit for the model, with n = 3004 for Non-Hispanic and n = 478 for Hispanic (CFI = .944; NFI = .942 NNFI = .932 RMSEA = .115).

Race

Strong factorial invariance provided a good fit for the model, with n = 2351 for White and n = 97 for Black (CFI = .936; NFI = .933, NNFI = .922 RMSEA = .124).

School size

Strong factorial invariance provided a very good fit for the model, with N = 1242 for small school size (<200 6th graders), and N = 2309 for large school size (>200 6th graders) (CFI = .967; NFI = .965 NNFI = .960 RMSEA = .089).

Scale reliabilities

Strong factorial invariance was adequate for all of the subsamples, so Cronbach’s Coefficient Alpha was calculated only for the total sample (see Figure 1 for the structure). Coefficient Alpha = .90 for Social Pressure, .81 for Social Anxiety, and .82 for Opportunity.
Discussion

Examination of fit indices of each of four models of factorial invariance indicate that strong factorial invariance of the three-factor model of Temptations to Try Alcohol Scale has a good fit across all subgroups, with most fit indices of NFI, NNFI and CFI around .95. This provides empirical support for the internal validity of the scale.

Although NFI, NNFI and CFI fit indices for strong factorial invariance are above .90 for all subgroups, which indicates acceptable fit of the model, the analysis of ΔCFI is less consistent across subgroups. For gender, ethnicity, and race, ΔCFI is slightly higher than proposed cut off value (−0.01), suggesting that there could be some differences in error measurement within these two subgroups, and further research is needed to explore this inconsistency. However, the highest level of invariance can be difficult to obtain in most measures and the results are not indicators of unreliable measure. Also, unequal and small sample sizes for race and ethnicity subgroups could cause the relatively high RMSEA values. Sample sizes of less than 250 impact the reliability of RMSEA estimate (Hu & Bentler, 1999).

These results demonstrate that Temptations to Try Alcohol Scale can be used in multiple subgroups and legitimate comparisons can be made among manifest variables across different populations. The Temptations to Try Alcohol Scale is invariant across factor loadings and error variances across gender, ethnicity, race and school size, and it is a psychometrically sound measure.
