Abstract

**Background:** Young adults (ages 18-44) have increased emergency department use for asthma and poor adherence to medications. The objective of this mixed-methods study was to understand experiences with and approaches to managing asthma, of which little is known in this age group.

**Methods:** Surveys (Asthma Control Questionnaire, Asthma Quality of Life Questionnaire) and 1:1 semi-structured interviews were used to explore experiences with asthma, symptoms, self-management behaviors, and relationship to asthma control and quality of life. Qualitative data were analyzed using content analysis techniques. Descriptive statistics and bivariate correlations were used to examine distributive characteristics and associations between variables.

**Results:** Forty urban adults participated (mean age 32.7 ± 6.2, 1σ). Coughing was reported nearly 46% more often than wheezing, with 42.5% (17/40) coughing until the point of vomiting most days. Most participants delayed using medication for symptoms due to misperceptions about inhalers. Higher symptom frequency and worse asthma control were associated with greater use of non-pharmacologic symptom management strategies (r=0.645, p<0.001; r=0.360, p=0.022, respectively). Five themes were identified regarding young adults experiences with asthma: (1) having asthma means being limited and missing out on life; (2) healthcare for asthma is burdensome and other things are more important; (3) there is not enough personal benefit in medical interactions to make preventive care worthwhile; (4) there is insufficient support and education about asthma for adults; and (5) people normalize chronic symptoms over time and find ways of coping that fit with their lifestyle.
Conclusions & Clinical Relevance: Young adults may tolerate symptoms without using quick-relief medication or seeking preventive care. Increasing engagement with preventive services will require decreasing perceived burdens and increasing the personal benefits of care. Evaluating for non-pharmacologic approaches to managing symptoms and asthma-related coughing may identify uncontrolled asthma. Enhanced training for clinicians in patient-centric asthma care may be needed.
Introduction

Despite the availability of effective treatment for asthma, the majority of young adults with asthma have persistently uncontrolled disease (ages 18-44 years, >58% uncontrolled asthma in 2016, U.S. population data).1 Adherence to controller medications has been estimated at 14.5-23.5%,2 with rates of emergency department use for asthma exacerbations than are higher than either younger or older age groups.3,4 These high-risk hallmarks suggest increased burden of asthma and an urgent need to improve outcomes in this age group.

Albeit having transparently poor asthma outcomes, little is known about asthma self-management in young adults.5-8 To date, most research in this area has been derived from pediatric and general/older adult populations.9-11 While there is some evidence that adolescent patterns of self-management (e.g. poor symptom recognition and declining medication adherence) extend into adulthood and contribute to worsening clinical outcomes,12,13 other research indicates that young adults might have unique needs and challenges.14,15 Lower-income urban young adults may be particularly at risk, having poorer health literacy, fewer resources, and decreased access to consistent high-quality care.15-17 However, information about this population is scarce.5,6,18,19

The ultimate goal of healthcare and related research is to improve outcomes and enable people to live well, unimpeded by disease. By extension, this means helping patients develop, implement, and maintain effective asthma self-management strategies, which are, in turn, contingent upon the willingness and ability of individuals to perform specific self-management tasks.20,21 Therefore, an important step in optimizing self-management is to first understand how people manage their asthma and why they do what they do.9,22 This knowledge is important for both clinicians and researchers, as oversight of key factors could impede ability to deliver care or
devise effective interventions. Thus, the purpose of this study was to explore young adults’ perceptions and experiences of asthma, usual approaches to asthma management, and underlying rationales for behaviors.
Methods

This was a mixed-methods observational study, including quantitative surveys, lung function, and 1:1 qualitative descriptive interviews. The study was approved by the University of Rochester as part of a broader interventional study for young urban adult smartphone users (NCT03648203, Ethics committee review October 10, 2017, RSRB67900).

Setting, sample

Forty patients were recruited from a safety-net resident-run primary care clinic in Western NY. This type of practice provides care to many lower socio-economic status individuals who might otherwise not have access to consistent primary care. Eligible participants were: (1) English speaking, (2) with persistent asthma by Expert Panel Report-3 (EPR3) criteria, (3) aged 18-44 years, (4) smartphone users, (5) not pregnant and (6) without confounding respiratory or cardiac diagnoses. A randomized roster of all patients aged 18-44 with asthma was generated for the participating practice using the electronic medical record (years 2018—2019). Letters were mailed to the first 140 patients on the randomized list notifying of intent to contact and offering patients a chance to "opt-out," but none elected to do so. This was followed by a screening phone call to consecutively listed patients 2-weeks later. Of the first 65 individuals reached by phone, 55 were eligible. Nine of these declined (unstated reasons), 6 were lost to contact, and 40 (72.7%) completed informed consent and participated in the study.

Data collection and Measures

All data were collected by a trained research assistant (RA) during a single home visit.  

Demographic and Asthma surveys. Surveys were used to gather data on asthma knowledge, symptoms, perceptions of severity and control, emergency department use,
satisfaction with asthma care, and demographics. Frequency of emergency use was measured by self-report to capture in- and out-of-network visits in the preceding year. All participants completed surveys via personal smartphone (paper copies were available but not utilized).

**Severity and control.** Asthma control was measured using the self-administered version of the paper-based *Asthma Control Questionnaire* (ACQ). The ACQ is a 7 item Likert scale survey with item and total scores ranging from 0-6. Cronbach alpha is ≥0.82 and test-retest reliability is ≥0.75). Lower scores indicate better asthma control, and a score of 1.5 has a positive predictive value of 0.88 for uncontrolled asthma. Asthma severity and control according to the National Heart Lung and Blood Institute EPR3 guidelines was determined by symptom frequency, nocturnal awakening, activity limitations, and use of short-acting beta-agonist (SABA).

**Forced expiratory volume (FEVI)** was measured during the in-home visit via Microlife Peak Flow Meter (PFM) which has validated accuracy to within 5% of the reading or ± 0.1 liters. Data were collected by the study RA, and patients were trained in meter use and maximal effort prior to measurement. Percentage predicted (FEV1%pred) was determined by the National Health and Nutrition Examination Survey (NHANES) criteria.

**Quality of life (QoL)** was measured using the self-administered version of the paper-based *Asthma Quality of Life Questionnaire* (AQLQ), which measures physical and emotional impact of disease. The AQLQ is a 32-item Likert scale survey with item and total scores ranging from 1-7. Cronbach alpha is ≥0.90 and test retest reliability is ≥0.95. Higher scores indicate better quality of life.

**Qualitative Interviews.** Following the surveys, each participant engaged in a private 1:1 semi-structured audio-recorded interview (average 43 minutes, range 26-94) with a trained
research assistant unknown to participants (JS; older, female, White, with social work background) using scaffolded interview questions derived from the Asthma Self-management Model \(^{21}\) (Box 1). All participants were aware of the purpose of the study. Questions were designed to explore experiences with asthma, perceptions of asthma and approaches to self-management, along with underlying rationales for self-management behaviors. Field note were recorded for each interview and shared with the research team prior to data analysis.

*Symptom/response card-sorting* \(^{34,35}\) was used to map each participant's usual symptom pattern and self-management responses and to elicit detailed information about experiences along with rationale for behaviors. For this activity, participants first identified their personal symptoms and self-management responses via a checklist developed in prior research. \(^{35,36}\) They were then given printed cards of the selected items and asked to arrange their symptoms/responses in order of occurrence, modifying words and cards as needed to create a visual depiction of their usual symptom/response pathway (Figure 1). Symptoms or responses that occurred more than once were quantitatively represented by additional cards. For example, participants who used an inhaler twice during their symptom pathway would include two inhaler cards in the map, next to the symptoms for which the inhaler would be used. Participants then described and discussed their symptom experiences, usual responses to symptoms, and rationales for behaviors, along with any commonly occurring situational differences in response.

**Data Analysis**

Qualitative data analysis occurred contiguously with data collection. Enrollment exceeded data saturation and no new codes were identified after the 35\(^{th}\) participant. Transcribed interviews and card-sorts were analyzed by JM, JD, KT, and AP using Nvivo12 and a qualitative descriptive consensus coding approach. \(^{37}\) Open coding was performed first. Content analysis
was used to analyze images and interviews for symptom type, frequency, severity, and patterns of symptoms/self-management responses, including use of pharmacologic and non-pharmacologic symptom management strategies.\textsuperscript{38} Frequencies were calculated as the percentage of participants who experienced a particular symptom \textit{and} the total number of instances that symptom was mentioned during interviews, as word frequency is a proxy indicator of importance to the individual.\textsuperscript{39,40} Lastly, data and codes were mapped using Xmind to develop thematic patterns and synthesized to define key concepts.\textsuperscript{41,42} Steps to enhance validity were: (1) structured memos; (2) member checking; and (3) peer-debriefing, and (4) use of participant identifiers for quotations in the manuscript, including race, sex, and age.\textsuperscript{43} Statistical analyses were performed using SPSS 25. Descriptive statistics were used to examine distributional characteristics of the data. Bivariate correlations were used to examine associations between linear variables including asthma control (ACQ), quality of life (AQLQ), emergency care, symptoms, and self-management strategies.

\textbf{Results}

Demographics are presented in Table 1. Participants were predominantly lower socioeconomic status, of minority ethnicity, with uncontrolled asthma (82.5\% uncontrolled by ACQ, 100\% uncontrolled by EPR3 classification).

Participants identified an average of 11 different symptoms (SD=4.4) and 10 self-management responses daily (SD=5) on the surveys. Two-thirds (25/40) reported having severe symptoms on a regular basis (e.g. difficulty speaking, cough to point of vomiting, severe chest pain most days or daily\textsuperscript{44}). For example:

\begin{quote}
\textit{P4: A typical day, it's like breathing through like a tiny hole...I feel like the elephant's sitting my chest. (Black, female, age 29)}
\end{quote}
Table 2 shows symptoms by frequency in interview transcripts versus card-sort images, including the percentage of participants who reported each symptom and the total number of instances a symptom occurred in each modality (interview transcripts vs. cardsort images). For example, coughing was reported by 90% of participants, but total instances of coughing (n=419) were 46% greater than total instances of wheezing (n=287), indicating that those with asthma-related coughing talked about coughing far more often than they talked about wheezing. Chest pain/pressure was also discussed more commonly than chest-tightness (2:1), and bothersome throat-clearing was frequently reported. Nearly 43% of participants (17/40) identified coughing to the point of vomiting regularly, as seen here:

P26: every morning I wake up, I can’t breathe, I start coughing hard, then throwing up...I keep a bucket beside my bed...” (Black, Female, age 40)

Participants discussed using non-pharmacologic symptom management strategies five times as often as using asthma medications (Table 2). Non-pharmacologic strategies included: (1) getting a drink; (2) restricting activity; (3) breathing control; (4) calming down; and (5) waiting/toughing it out. Nearly half used alternative medications to relieve symptoms (pain, allergy, cough/cold medication and rubs). While most described experiences with medical care, few sought healthcare to help manage symptoms (35%; 14/40). Trigger avoidance was also uncommon (37.5%; 15/40 participants) as many triggers were considered difficult or impossible to avoid (i.e. job exposures, weather).

As seen in Figure 2, which depicts card-sorts created by different participants, treatment thresholds (i.e. the point at which short-acting beta-agonists were used to treat active symptoms) were delayed in those with worse asthma control. Higher symptom frequency and worse asthma control were associated with greater use of non-pharmacologic strategies (r=0.645, p<0.00; r=0.360, p=0.022, respectively). Patients who used a higher percentage of nonpharmacologic
strategies for symptom control also had lower FEV1%pred (r=-0.341, p=0.031). A moderate association was seen between emergency department use and asthma quality of life (r=0.389; p=0.013). No significant association was found between age and frequency of symptoms or self-management responses.

**Summary of qualitative interview themes**

Five themes were identified: (1) having asthma means being limited and missing out on things you want to do (*Missing out on life*); (2) healthcare for asthma is burdensome and other things are more important (*High burden of medical care*); (3) there is not enough personal benefit from medical interactions to make preventive care worthwhile (*Low value/benefit of medical care*); (4) there is limited support and education about asthma for adults (*Insufficient education and support*); and (5) people normalize chronic symptoms over time, learn to "tough it out" and find ways of coping that fit with their lifestyle (*Coping and enduring*). The coding schema for these themes is displayed in **Figure 3** with supporting data presented in **Table 3**.

**Theme 1: Missing out on life**

Young adults believed that having asthma meant living with symptoms and being unable to do as much as people without asthma. All expressed a strong sense of missing out on life and being limited in the activities they wanted to do. This included decreased ability to be physically active, go out with friends, play with their children, attend important social events, and perform common activities of living, such as walking upstairs, doing laundry, grocery shopping, and household activities. The impact of uncontrolled asthma on daily life is evident in the following quotes:

*P1: I get frustrated, especially when I’m out for a good time and everybody’s sitting there laughing and I’m over here, choking because I can’t breathe.* (Black, male, age 26)
PERCEPTIONS OF ASTHMA MANAGEMENT IN YOUNG ADULTS

P13: I would definitely go out more if I could, you know, breathe. I used to go to the park and walk around—we don’t do any of that stuff anymore. (Multiracial, female, age 39)

Theme 2: High burden of medical care

While feeling that asthma substantially limited activities and quality of life, participants indicated that trying to manage asthma was too difficult, specifically with regards to accessing medications and medical care. Many indicated their life was busy and chaotic. Finding time to get to appointments required too much time and effort, and often conflicted with other personal needs. A recurrent challenge was scheduling and keeping appointments, as office hours occurred during the working week, which required taking time off work to get to visits. As one woman explained:

P37: It’s too much effort. What’s it doing for me? I only get ten personal days which are maxed out. After that, I’m gonna lose money and I’ve gotta take care of home. My asthma doesn’t seem like a priority with my doctors, so I feel like, “Why am I gonna stress myself out to go? (Black, female, age 25)

Many indicated taking care of kids/family, getting to work, and paying the bills were more important than managing asthma. Because medical management conflicted with these priorities, it was often deferred until urgent care was required.

P10: It just doesn’t work for me. I don’t make the time to take care of my asthma because I’m always so tired and busy, and my schedule is hectic…If it’s not bothering me at the time, I don’t mention [asthma] at all…unless it’s to the point where I can’t breathe….(Black, female, age 30)

Difficulties with insurance (lapses, medications not approved by plan) and financial challenges were another source of burden, including cost of medications, co-pays, parking fees, transportation costs, and lost income.

Theme 3: Low value/benefit of medical care
A dominant theme throughout interviews was that there was not enough benefit from asthma-related preventive care to make it worth the effort of engaging. Many indicated the medical care they received in the past had not helped them much. Combined with Theme 2, this translated to a high burden of accessing care with little perceived personal benefit:

P4: I kind of pulled myself back from going to the doctor because I felt like it wasn’t helping enough. I felt like okay….I’ll just take care of it myself. (Black, female, age 29)

P6: I feel like the cost benefit ratio is not fair going to my primary care. If I have to go anyways, then I’ll talk to them about it. But if it’s specifically for my asthma, I’m not doing that. (Black, female, age 26)

Lack of benefit occurred in two main areas: (1) medications do not work well, and (2) healthcare interactions don’t help much.

**Medications do not work.** Of forty participants, nine had no rescue inhaler (22.5%). Of those who did, 83.8% (26/31) indicated that they often avoided taking it because they felt the medication either didn’t work at all or didn’t work fast enough. As one man commented, "I don’t see the relief so my instinct is don’t take it" (P17, Hispanic/Latino, male, age 37). Consequently, participants often used non-pharmacological methods of managing symptoms (e.g. activity restriction, breathing control) instead of prescribed therapy to relieve active symptoms (92.5%; 37/40 participants). Many were unaware of differences between control and rescue medication (50%; 20/40). For example, "I use a blue one and a red one…they’re both the exact same thing" (P7, White, male, age 29), and "Control inhaler? I don’t even know what that is..." (P2, Black, female, age 41). Among those aware of being prescribed control medication, similar beliefs regarding ineffectiveness were voiced as a rationale for not using:

P15: That’s one they hand me for control. I’ve never seen a difference what so ever…so, it gets tossed to the side [because] it does not work. (White, male, age 39)
**Healthcare interactions don't help.** In interviews, nearly 80% (32/40) of participants expressed frustration regarding their asthma-related healthcare. On survey, 50% (20/40) indicated dissatisfaction with their asthma care, and 52.5% (21/40) reported feeling that healthcare providers (HCP; commonly referred to as "doctor") did not help when it came to managing asthma. Greater satisfaction with care was associated with better asthma control ($r=0.411$, $p=0.008$) and marginally associated with quality of life ($r=0.30$, $p=.058$). As seen in Table 3, this included recurrent sub-themes that the HCP did not listen to and prioritize patient concerns, did not seem caring or connected, and did not follow up on treatment plans to evaluate for effectiveness. In particular, patients disliked seeing different HCPs, as this limited ability to develop a relationship and required them to repeat information at visits. Furthermore, many felt HCPs did not view asthma as a priority and were focused on other health and psychiatric issues to the exclusion of asthma (e.g. mental health, comorbidities, obesity). Participants indicated that HCPs rarely asked specific questions about asthma. For example:

*P1*: When I go the doctor, they ask about all my other stuff, but they never ask about my asthma. *(Black, male, age 26)*

*P37*: They usually ask something like, “have you had trouble breathing in the last year?” Real quick like it isn’t that important … I say “it’s OK,” because it is fine in the moment and I can’t go back deeply like that on the spot. *(Black, female, age 25)*

Others reported feeling rushed during visits and felt the doctor didn’t give adequate attention to their concerns that medications weren’t working or that they had trouble obtaining medications.

*P7*: I don’t feel like they listen. They be there for five minutes and then you’re done…They just keep giving me different medications…Why?* *(White, male, age 29)*

*P8*: The doctors are so busy, we don’t really get to talk [about asthma]. *(White, female, age 34)*
Theme 4: Insufficient education and support for adults with asthma

In addition to the high burden of medical care and perceived lack of benefit, participants indicated that they did not receive support or education for managing asthma as an adult. As one man commented, "I don’t see a lot of doctors explaining to people what asthma is, how it can affect you. It’s like “Hey you got asthma, take an inhaler" (P17, Hispanic/Latino male, age 37). Some recalled receiving asthma education as pediatric patients but indicated they were unable to recall what they learned during childhood. Consequently, participants felt they did not know enough as adults to manage asthma effectively. Several specifically noted that the withdrawal of pediatric supports made it harder to control their asthma as adults. For instance:

P10: [as a kid] the doctor explained it to me. I was good back then, I was controlled. But I had help you know? I had parents who stayed on me, I went to school and my nurse stayed on me...
(Black, female, age 30)

P37: coming from pediatrics to my primary care doctor, no one ever told me anything about asthma, so I’m just going based off of what my mom told me. I don’t really know a lot besides you have a problem breathing. That’s all I know. (Black, female, age 25)

The two most commonly identified areas of concern to participants were lack of understanding about managing asthma in general (80%, 32/40) and asthma medications (65%; 26/40). This included knowledge about which medication to use, how much to use, when to use it, side effects, and expected onset of symptom relief. This interview finding was substantiated by surveys: 87.5% of participants thought all inhalers worked immediately and 62.5% (25/40) believed overusing inhalers could lead to addiction.

Understanding of asthma control was poor. Most participants thought asthma was uncontrolled only if symptoms occurred multiple times daily (35%; 14/40), did not resolve with SABA use (25; 10/40), occurred more often than usual (17.5%; 8/40), or they could not figure
out how to handle symptoms (15%; 7/40). Most (80%) believed that the primary purpose of controlling asthma was to decrease medication use, prevent dependency, and avoid complications from over-using medication, which contributed to decisions to minimize medication use even when symptomatic. As one woman expressed:

\textit{P12: I stopped because I was addicted to always doing [the inhaler] if I wheezed. (Black, female, age 27)}

Even those who felt knowledgeable (12.5%; 5/40) had poor understanding of effective self-management. This is illustrated in the following quote:

\textit{P21: I've been taught a lot of stuff about asthma... they say you can control it by using your pumps and steam in the bathroom. I grab this [inhaler] and take like 8 or 9 pulls, that don’t work ... I sit in the bathroom 4 or 5 hours in the steam. (Black, female, age 29)}

**Theme 5: Coping and Enduring**

The large majority of participants had daily symptoms (87.5%; 35/40 participants), and more than half reported experiencing anxiety or panic related to symptoms (21/40). Symptoms that occurred on a regular basis were normalized over time (100%; 40/40 participants) as seen here: "I guess I've just been living with it, so it's normal" (P6, Black, female, age 26). Furthermore, as ability to tolerate symptoms increased over time, use of medication correspondingly decreased. Instead of using medication, many waited for symptoms to resolve and tried to “tough it out” or held off on taking medications as long as possible (65%; 26/40 participants).

\textit{P1: I'm used to wheezing. I go through this all the time, so I don’t always take [the inhaler]. (Black, male, age 26)}

Many participants preferred using non-pharmacologic symptom management strategies (87.5%), as this helped to reduce medication use and increased their sense of control over
asthma. Medications were typically reserved for bothersome symptoms with greater than usual severity. Participants often did not use inhalers for "normal" symptoms that could be managed by other means, such as restricting activity to reduce symptom burden.

P20: I try not to use my medicine. My doctor he told me over using it ain’t good. I don’t wanna get immune to it. (Black, male, age 37)

P31: I ignore it until I can’t handle it. I keep my normal daily activities to a minimum at a regular basis, so I don’t need [the inhaler.] (Caucasian, male, age 39)
Discussion

Our findings show the extensive and pervasive burden of disease experienced by young adults living with uncontrolled asthma. Many participants in this study experienced debilitating daily symptoms for which they chose not to use quick-relief medication or seek medical attention due to the difficulty of accessing care and the limited perceived benefit of prior healthcare interactions and medications. Instead, non-pharmacologic symptom management strategies were often used to control symptoms (e.g. restricting activity). Thus, even though asthma "ruined" their quality of life and limited ability to do everyday activities, many found enduring symptoms to be less burdensome than engaging in preventive healthcare.

This highlights a substantial healthcare problem that is applicable to a range of chronic diseases. How can we expect to increase engagement in preventive care if the perceived burden of accessing care is greater than the burden of uncontrolled disease? In order to improve individuals' self-management and population health outcomes we must recognize that the burden of disease not only encompasses the effect of illness on health and quality of life, but also the burden of disease management – specifically, the enormous effort required to manage a complex illness effectively in a non-user-friendly healthcare environment. Young adults may be particularly at risk in this regard, as transition to adulthood and autonomous self-care is often accompanied by loss of pediatric support services and an established primary care provider. While there are no data on the frequency of preventive asthma visits in young adults, other chronic disease literature indicates preventive care may be half that of adults over age 45, thus explaining elevated rates of emergency care utilization and declining medication adherence in this population.
Ironically, the low personal value of healthcare interactions for young adults with asthma could be partially attributable to "value-based" approaches to care, which require HCPs to accomplish numerous preventive tasks within the short time allotted for a standard visit (e.g. smoking cessation counseling, depression screening). Thus, the disturbing observation by participants that HCPs were often preoccupied with other issues holds strong face-validity. While health-maintenance items are important from a population health perspective, it is imperative to recognize that such agendas may not correspond with patients' views of their healthcare needs, and that in prioritizing population health we risk marginalizing and alienating individuals. This raises the ethical question: Whose values should be prioritized in value-based healthcare?

It is almost certain that improving outcomes will require modifying current approaches to preventive care, including minimizing barriers (e.g. making care convenient) and maximizing benefits (making care meaningful and effective from patient perspectives). This might include more aggressive treatment and follow-up to ensure that asthma medications (quick relief and controller) are being used at the proper dose and technique to quickly and effectively reduce symptoms. Additionally, greater intentionality on the part of clinicians might be needed to reengage patients who have been alienated by prior experiences, as these individuals might not report symptoms. Ultimately, changing outcomes will entail carving out time to systematically assess and educate adult patients about asthma, or devising alternate care models that can address critical gaps in care.

Lastly, our findings suggest that young adults normalize regularly occurring symptoms and learn to tolerate progressively greater symptom severity over time. Clinician training may be needed to increase awareness and to promote accuracy of clinical assessments. Asking about
specific symptoms along with symptom management strategies could help identify those who are not well-controlled, as greater numbers of non-pharmacologic strategies suggest higher levels of uncontrolled symptoms. It is also worth observing that coughing was the most commonly mentioned symptom, with many coughing to the point of vomiting. This finding, similar to adolescent populations, suggests that coughing may be a particularly bothersome symptoms of asthma from patients' perspectives. Clinicians may want to monitor for the presence of asthma-related coughing and educate patients how controller medication can reduce coughing to promote adherence. Lastly, it may be useful to consider word-choices when assessing symptoms. While "chest tightness" is the accepted clinical term, "chest pain" and "chest pressure" may be more reflective of the patient experience. Incorporating patient-centric terminology validates individuals' experiences and might be useful in developing therapeutic relationships.

Limitations. Participants in this study were predominantly lower socio-economic status, young, urban adults from a hospital-based primary care clinic that had higher rates of uncontrolled asthma than the general U.S. population (61.9% vs. 82.5%). Findings may not be generalizable to non-equivalent populations or may only be reflective of similar patients with uncontrolled asthma. Additionally, data were collected at single time point from a small sample of developmentally diverse adults (emerging and midlife), and distinctions between age groups and changes over time were not identified. Repetition in a more diverse sample with attention to age-related changes in self-management may be warranted. Nonetheless, our findings indicate concerning patterns of suboptimal asthma management in at-risk young adults, and highlight the urgent need to improve clinical assessment and asthma management, as well as avenues for future research.
Conclusions

Young adults with uncontrolled asthma may normalize symptoms over time and elect to use non-pharmacologic symptom management strategies instead of using asthma medications or seeking preventive care that could lead to controller medication. Living with recurrent symptoms may be viewed as less burdensome than engaging in preventive healthcare. Enhanced training for clinicians in patient-centric asthma care may be needed to achieve meaningful change in outcomes for patients.

### Notes

- *Asthma Control Questionnaire (range 0-6), lower scores represent better asthma control, a score of ≥1.5 has 88% positive predictive value for uncontrolled asthma;*  
- *Asthma Quality of Life Questionnaire (range 1-7), higher scores represent better quality of life*

**Notes.** Instances = number of times a symptom or response was used in a card-sort or mentioned by a participant during the course of the interview (excluding the interviewer's words).
I'm limited with a lot of things because of my asthma. Sometimes I don't like to go out because I get shortness of breath, I get dizzy. Grocery shopping and laundry are... it's triggered me. It's the part that I can't breathe... I haven't been active in sports or played basketball, did anything like that in a few years. [But] I couldn't go because it was hot outside, and she was upset... how do you explain that to people?

Other things are more complicated and difficult: ACCESING CARE

Getting the pill

Planning ahead

Getting access to family

Time issues are more

Other things are hard

Getting the pill

Getting access to family

Planning ahead

Getting access to family
I'm coughing till I'm about to throw up…

Sometimes I [take the inhaler] but I'm used to waiting it out… I don't think about it till it's too late and I'm already in trouble.

When I start wheezing, I just usually just sit down and do my deep breathing exercises. Try and relax. Try not to think about it.

The medicine's not working. And the [doctor] said “make sure to get it, take it on time.” I said, I do that every day and it's still like this.

I feel like I just go see doctors. I don't feel like they actually try to fix it or figure it out. It's just 'okay there's this thing'.

I got tired of asking for refills because my doctor looks at me like, 'hey, it's not gonna work anyways.' Honestly, nothing controls my symptoms. I'll take my rescue inhaler about 4 times a day… I'll be like, 'Ugh, this thing is just…'

The doctor and discussed asthma. As a kid, they told me how I should be taking my medicine, but I didn't really follow through with it. Now they just tell me "you just got to stop smoking".

When I first started noticing symptoms, I thought it was asthma but it turned out to be something else. Now I'm not sure of the difference between a control and rescue inhaler is something that holds you off probably until you make it to the hospital.

I feel like I'm not connected with my doctor… just my own personal thing [so] I go to the emergency room.

My asthma doesn't seem like it's a priority with my doctors… I just feel like it's something on the list to check off.
PERCEPTIONS OF ASTHMA MANAGEMENT IN YOUNG ADULTS

P22 (HL, F, 23Y): Tough it out... Take a deep breath. Wait it out... let's try to tough it out, control my breathing on my own.

P23 (AS, F, 23Y): Tough it out, tough it out... I do that with everything. I feel like I should be breathing more but I'm just so used to this that it's normal for me.

P24 (MR, F, 36Y): I'll wait to take my pump until last. And the reason I do that is because I want to try my hardest to get through it without steroids.

Notes: Participant quotes are identified by participant number (P#), followed by (Race, Sex, Age in years). Race: A=Asian, B=Black, HL=Hispanic/Latino, MR=Multiracial, W=White. Sex: F=Female, M=Male.
Box 1. Sample interview questions

1. Talk to me about your asthma. Can you tell me about your experiences?
   a. What are your experiences getting healthcare for asthma?
   b. What have you been taught about your asthma?
   c. What are the biggest challenges in managing or treating your asthma?

2. How do you feel about your current asthma management?
   a. What works and/or doesn’t work for you?

3. What kinds of things help you manage your asthma better?

4. What does having well controlled asthma mean to you?

5. Tell me about your asthma medications:
   a. What is a control inhaler to you? What is a rescue inhaler?
   b. How do you feel about taking daily control medication (___)? How do you feel about taking rescue medication (___)? Describe how/when/where you use it or not use it. How do you decide?

6. With card-sort activity, after mapping symptoms/responses: Think about the last time you had asthma symptoms. Describe exactly what you experienced and what you did to manage the symptoms.
   a. What kinds of things do you usually do to manage your asthma? (medical or non-medical)
   b. Explain where and why you do each thing.
   c. When you take medication, how does it work?
FIGURE 1. Image of participant card-sort showing perceived asthma symptoms and specific self-management responses to symptoms (top-down order of occurrence; P9)
FIGURE 2. Comparison of symptoms, self-management, asthma control, and quality of life between adults with well-controlled, marginally controlled, not well-controlled, and very poorly controlled asthma using card-sorts.
FIGURE 3. Key themes from qualitative interviews and supporting coding schema
