1. Introduction

A first order system of difference equations:

\[ \begin{align*}
    x_{n+1} &= f(x_n, y_n), \\
    y_{n+1} &= g(x_n, y_n),
\end{align*} \]

where \( f, g : \mathbb{R}^2 \rightarrow \mathbb{R} \), \( f, g \) are continuous functions, is \textit{competitive} if \( f(x, y) \) is nondecreasing in \( x \) and nonincreasing in \( y \), and \( g(x, y) \) is nonincreasing in \( x \) and nondecreasing in \( y \).

System (1) where the functions \( f \) and \( g \) are monotonic character opposite the monotonic character in competitive system is called \textit{anticompetitive}; see [1, 2].

In this paper, we consider the following anticompetitive systems of difference equations:

\[ \begin{align*}
    x_{n+1} &= \frac{y_1 y_n}{B_1 x_n + y_n}, \\
    y_{n+1} &= \frac{\beta_2 x_n}{B_2 x_n + y_n},
\end{align*} \]

where all parameters are positive numbers and the initial conditions \((x_0, y_0)\) are arbitrary nonnegative numbers such that \( x_0 + y_0 > 0 \). In the classification of all linear fractional systems in [3], System (2) was mentioned as system (18, 18). We also consider systems

\[ \begin{align*}
    x_{n+1} &= \frac{\alpha_1 y_n}{A_1 x_n + y_n}, \\
    y_{n+1} &= \frac{\alpha_2 + \beta_2 x_n}{y_n},
\end{align*} \]

with \( x_0 > 0 \), \( y_0 > 0 \), which were labeled as systems (18, 23) and (16, 23), respectively, in [3]. Three systems have interesting and different dynamics. While System (2) has all bounded solutions, most of solutions of Systems (3) and (4) are unbounded. Another major difference is the existence of the unique period-two solution for (2) and, in a special case, the abundance of such solutions, while neither (3) nor (4) has period-two solutions. We show that every solution of System (3) converges to the unique equilibrium or is approaching \((0, \infty)\) and so System (3) gives an example of a semistable equilibrium point. Finally, we show that all solutions of (4) which start on the stable set converge to the unique equilibrium, while all solutions which start off the stable set are approaching \((0, \infty)\) or \((\infty, 0)\). We also get that...
for some special values of parameters, Systems (4) and (3) can be decoupled and explicitly solved.

Competitive systems of the form (1) were studied by many authors such as Clark and Kulenović [4], Hess [5], Hirsch and Smith [6], Kulenović and Merino [7], Kulenović and Nurkanović [8], Garić-Demirović et al. [9, 10], and Smith [11, 12]. Precise results about the basins of attraction of the equilibrium points have been obtained in [13].

The study of anticompetitive systems started in [1] and has advanced since then; see [2]. The principal tool of study of anticompetitive systems is the fact that the second iterate of the map associated with anticompetitive system is competitive map and so elaborate theory for such maps developed recently in [6, 14, 15] can be applied.

The major result on a global behavior of System (2) is the following theorem.

Theorem 1. (a) Assume that \(B_1 < B_2\). Then the unique positive equilibrium point \((x, y)\) of System (2) is locally asymptotically stable with the basin of attraction \(\mathcal{B}(E) = (0, \infty)^2\). The unique period-two solution \(\{(x_1, 0), (0, B_2/B_1)\}\) is a saddle point and its basin of attraction is the union of coordinate axes without the origin, that is, \(\mathcal{B}((x_1, 0)) = \{(x, 0) \mid x > 0\} \cup \{(0, y) \mid y > 0\}\).

(b) Assume that \(B_1 > B_2\). Then every solution of System (2) converges to the period-two solution \(\{(x_1, 0), (0, B_2/B_1)\}\) or to the equilibrium \((x, y) = (0, 0)\). More precisely, there exists a set \(\mathcal{C} = \{(x, (y/x)x) : x > 0\} \subset \mathcal{R} = (0, \infty)^2\) which is the basin of attraction of \((x, y) = (0, 0)\). The set \(\mathcal{C}\) has the property that for \(\mathcal{W}_- := \{x \in \mathcal{R} \mid \exists y \in \mathcal{C} \text{ with } x \leq y\}\)

\[= \{(x, y) : y > \frac{y}{x}x \geq 0\}, \]

\(\mathcal{W}_+ := \{x \in \mathcal{R} \mid \exists y \in \mathcal{C} \text{ with } y \leq x\}\)

\[= \{(x, y) : 0 \leq y < \frac{y}{x}x\}, \tag{5} \]

the following holds.

(i) If \((x_0, y_0) \in \mathcal{W}_+\), then

\[\lim_{n \to \infty} (x_{2n}, y_{2n}) = P_1, \quad \lim_{n \to \infty} (x_{2n+1}, y_{2n+1}) = P_2. \tag{6} \]

(ii) If \((x_0, y_0) \in \mathcal{W}_-\), then

\[\lim_{n \to \infty} (x_{2n}, y_{2n}) = P_2, \quad \lim_{n \to \infty} (x_{2n+1}, y_{2n+1}) = P_1. \tag{7} \]

(c) Assume that \(B_1 = B_2\). Then every solution of System (2) is equal to either the period-two solution \(\{(B_1, x_0 + y_0), (B_1, x_0)\}\) or to the equilibrium \((x, y) = (B_1, 1)\), where \(D = B_2/\gamma_1\) and \(\bar{x} = \sqrt{B_2/\gamma_1}/(B_1 + 1)\).

2. Preliminaries

We now give some basic notions about competitive systems and maps in the plane of the form (1), where \(f\) and \(g\) are continuous functions, \(f(x, y)\) is nondecreasing in \(x\) and nonincreasing in \(y\), and \(g(x, y)\) is nonincreasing in \(x\) and nondecreasing in \(y\) in some domain \(A\) with nonempty interior.

Consider a map \(T = (f, g)\) on a set \(\mathcal{R} \subset \mathcal{R}^2\), and let \(E \in \mathcal{R}\). The point \(E \in \mathcal{R}\) is called a fixed point if \(T(E) = E\). An isolated fixed point is a fixed point that has a neighborhood with no other fixed points in it. A fixed point \(E \in \mathcal{R}\) is an attractor if there exists a neighborhood \(\mathcal{U}\) of \(E\) such that \(T^n(x) \to E\) as \(n \to \infty\) for \(x \in \mathcal{U}\); the basin of attraction is the set of all \(x \in \mathcal{R}\) such that \(T^n(x) \to E\) as \(n \to \infty\). A fixed point \(E\) is a global attractor on the set \(\mathcal{R}\) if \(E\) is an attractor and \(\mathcal{R}\) is a subset of the basin of attraction of \(E\). If \(T\) is differentiable at a fixed point \(E\) and if the Jacobian \(J_f(E)\) has one eigenvalue with modulus less than one and a second eigenvalue with modulus greater than one, \(E\) is said to be a saddle. See [16] for additional definitions.

Definition 2. Let \(T = (f, g)\) be a continuously differentiable vector function and let \(U\) be a neighborhood of a saddle point \((\bar{x}, \bar{y})\) of (1). The local stable manifold \(\mathcal{W}_{\text{loc}}\) is the set

\[\mathcal{W}_{\text{loc}}((\bar{x}, \bar{y})) = \left\{(x, y) : T^n(x, y) \in U \forall n \geq 0 \wedge \lim_{n \to \infty} T^n(x, y) = (\bar{x}, \bar{y})\right\}. \tag{8} \]

The global stable manifold \(\mathcal{W}^s\) of a saddle point \((\bar{x}, \bar{y})\) is the set

\[\mathcal{W}^s((\bar{x}, \bar{y})) = \left\{(x, y) : \lim_{n \to \infty} T^n(x, y) = (\bar{x}, \bar{y})\right\}. \tag{9} \]

The map \(T\) may be viewed as a monotone map if we define a partial order on \(\mathcal{R}^2\) so that the positive cone in this new partial order is the fourth (resp. first) quadrant. Define a south-east (resp. north-east) partial order \(\leq_{se}\) (resp. \(\leq_{ne}\)) on \(\mathcal{R}^2\) so that the positive cone is the fourth quadrant (resp. first quadrant), that is, \((x_1, y_1) \leq_{se} (x_2, y_2)\) (resp. \((x_1, y_1) \leq_{ne} (x_2, y_2)\)) if and only if \(x_1 \leq x_2\) and \(y_1 \geq y_2\) (resp. \(x_1 \leq x_2\) and \(y_1 \leq y_2\)). For \(x, y \in \mathcal{R}^2\), the order interval \([x, y]\) is the set of all \(z\) such that \(x \leq z \leq y\). The map \(T\) is called competitive (resp. cooperative) on a set \(S\) if \(x <_{se} w\) (resp. \(v <_{ne} w\)) implies \(T(v) <_{se} T(w)\) (resp. \(T(v) <_{ne} T(w)\)).

Two points \(v, w \in \mathcal{R}^2\) are said to be related if \(v \leq w\) or \(w \leq v\). Also, a strict inequality between points may be defined as \(v < w\) if \(v \leq w\) and \(v \neq w\). A stronger inequality may be defined as \(v \ll w\) if \(v_1 < w_1\) and \(v_2 < w_2\). A map \(f : \text{Int} \mathcal{R}^2_+ \to \text{Int} \mathcal{R}^2_+\) is strongly monotone if \(v < w\) implies that \(f(v) \ll f(w)\) for all \(v, w \in \text{Int} \mathcal{R}^2_+\). Clearly, being related is invariant under the iteration of a strongly monotone map. Differentiable strongly monotone maps have Jacobian with constant sign configuration

\[
\begin{pmatrix}
+ & - \\
- & +
\end{pmatrix}
\tag{10}
\]

The mean value theorem and the convexity of \(\mathcal{R}^2_+\) may be used to show that \(T\) is monotone, as in [17].

For \(x = (x_1, x_2) \in \mathcal{R}^2\), define \(Q(x)\) for \(l = 1, \ldots, 4\) to be the usual four quadrants based at \(x\) and numbered in
a counterclockwise direction, for example, $Q_1(x) = \{ y = (y_1, y_2) \in \mathbb{R}^2 : x_1 \leq y_1, x_2 \leq y_2 \}$. We now state three results for competitive maps in the plane.

The following definition is from [11].

**Definition 3.** Let $\mathcal{S}$ be a nonempty subset of $\mathbb{R}^2$. A competitive map $T : \mathcal{S} \to \mathcal{S}$ is said to satisfy condition $(O+)$ if for every $x, y$ in $\mathcal{S}$, $T(x) \preceq y$ implies $x \preceq y$, and $T$ is said to satisfy condition $(O−)$ if for every $x, y$ in $\mathcal{S}$, $T(x) \succeq y$ implies $x \succeq y$.

The following theorem was proved by de Mottoni-Schiaffino for the Poincaré map of a periodic competitive Lotka-Volterra system of differential equations. Smith generalized the proof to competitive and cooperative maps [11, 12].

**Theorem 4.** Let $\mathcal{S}$ be a nonempty subset of $\mathbb{R}^2$. If $T$ is a competitive map for which $(O+)$ holds, then for all $x \in \mathcal{S}$, $\{T^n(x)\}$ is eventually componentwise monotone. If the orbit of $x$ has compact closure, then it converges to a fixed point of $T$. If instead $(O−)$ holds, then for all $x \in \mathcal{S}$, $\{T^{−n}(x)\}$ is eventually componentwise monotone. If the orbit of $x$ has compact closure in $\mathcal{S}$, then its omega limit set is either a period-two orbit or a fixed point.

The following result is from [11], with the domain of the map specialized to be the cartesian product of intervals of real numbers. It gives a sufficient condition for conditions $(O+)$ and $(O−)$.

**Theorem 5.** Let $\mathcal{R} \subset \mathbb{R}^2$ be the cartesian product of two intervals in $\mathcal{R}$. Let $T : \mathcal{R} \to \mathcal{R}$ be a $C^1$ competitive map. If $T$ is injective and det $J_T(x) > 0$ for all $x \in \mathcal{R}$, then $T$ satisfies $(O+)$, i.e., $T$ is injective and det $J_T(x) < 0$ for all $x \in \mathcal{R}$, then $T$ satisfies $(O−)$.

The following result is a direct consequence of the Trichotomy Theorem of Dancer and Hess, see [5, 15, 18], and is helpful for determining the basins of attraction of the equilibrium points.

**Corollary 6.** If the nonnegative cone with respect to the partial order $\preceq$ is a generalized quadrant in $\mathbb{R}^2$ and if the competitive map $T : \mathbb{R}^2 \to \mathbb{R}^2$ has no fixed points in $[u_1, u_2]$ other than $u_1$ and $u_2$, then the interior of $[u_1, u_2]$ is either a subset of the basin of attraction of $u_1$ or a subset of the basin of attraction of $u_2$.

The next two results are from [15, 18].

**Theorem 7.** Let $T$ be a competitive map on a rectangular region $\mathcal{R} \subset \mathbb{R}^2$. Let $\mathcal{R} \in \mathcal{R}$ be a fixed point of $T$ such that $\Delta := \mathcal{R} \cap \text{int}(Q_1(\mathcal{R}) \cup Q_2(\mathcal{R}))$ is nonempty (i.e., $\Delta$ is not the NW or SE vertex of $\mathcal{R}$), and $T$ is strongly competitive on $\Delta$. Suppose that the following statements are true.

(a) The map $T$ has a $C^1$ extension to a neighborhood of $\Delta$.

(b) The Jacobian matrix of $T$ at $\Delta$ has real eigenvalues $\lambda, \mu$ such that $0 < |\lambda| < \mu$, where $|\lambda| < 1$, and the eigenspace $E^1$ associated with $\lambda$ is not a coordinate axis.

Then there exists a curve $\mathcal{C} \subset \mathcal{R}$ through $\Delta$ that is invariant and a subset of the basin of attraction of $\mathcal{R}$, such that $\mathcal{C}$ is tangential to the eigenspace $E^1$ at $\Delta$, and $\mathcal{C}$ is the graph of a strictly increasing continuous function of the first coordinate on an interval. Any endpoints of $\mathcal{C}$ in the interior of $\mathcal{R}$ are either fixed points or minimal period-two points. In the latter case, the set of endpoints of $\mathcal{C}$ is a minimal period-two orbit of $T$.

**Theorem 8.** Let $\mathcal{J}_1, \mathcal{J}_2$ be intervals in $\mathcal{R}$ with endpoints $a_1, a_2$ and $b_1, b_2$ with endpoints, respectively, with $a_1 < a_2$ and $b_1 < b_2$, where $-\infty < a_1 < a_2 < \infty$ and $-\infty < b_1 < b_2 < \infty$. Let $T$ be a competitive map on a rectangle $\mathcal{R} = \mathcal{J}_1 \times \mathcal{J}_2$ and $\mathcal{R} \in \text{int}(\mathcal{R})$. Suppose that the following hypotheses are satisfied.

(1) $T(\text{int}(\mathcal{R})) \subset \text{int}(\mathcal{R})$ and $T$ is strongly competitive on $\text{int}(\mathcal{R})$.

(2) The point $\mathcal{R}$ is the only fixed point of $T$ in $(Q_1(\mathcal{R}) \cup Q_2(\mathcal{R})) \cap \text{int}(\mathcal{R})$.

(3) The map $T$ is continuously differentiable in a neighborhood of $\mathcal{R}$, and $\mathcal{R}$ is the saddle point.

(4) At least one of the following statements is true.

(a) $T$ has no minimal period-two orbits in $(Q_1(\mathcal{R}) \cup Q_2(\mathcal{R})) \cap \text{int}(\mathcal{R})$.

(b) det $J_T(x) > 0$ and $T(x) = \mathcal{R}$ only for $x = \mathcal{R}$.

Then the following statements are true.

(i) The stable manifold $W^s(\mathcal{R})$ is connected and it is the graph of a continuous increasing curve with endpoints in $\partial \mathcal{R} \cap \text{int}(\mathcal{R})$ is divided by the closure of $W^s(\mathcal{R})$ into two invariant connected regions $W^s$ ("below the stable set"), and $W^u$ ("above the stable set"), where

$$W^s := \{ x \in \mathcal{R} \setminus W^u(\mathcal{R}) : \exists x' \in W^u(\mathcal{R}) \text{ with } x \preceq x' \} \cap \text{int}(\mathcal{R})$$

$$W^u := \{ x \in \mathcal{R} \setminus W^s(\mathcal{R}) : \exists x' \in W^s(\mathcal{R}) \text{ with } x' \preceq x \} \cap \text{int}(\mathcal{R}).$$

(11)

(ii) The unstable manifold $W^u(\mathcal{R})$ is connected and it is the graph of a continuous decreasing curve.

(iii) For every $x \in W^u$, $T^m(x)$ eventually enters the interior of the invariant set $Q_1(\mathcal{R}) \cap \mathcal{R}$, and for every $x \in W^u$, $T^m(x)$ eventually enters the interior of the invariant set $Q_2(\mathcal{R}) \cap \mathcal{R}$.

(iv) Let $m \in Q_1(\mathcal{R})$ and $M \in Q_2(\mathcal{R})$ be the endpoints of $W^u(\mathcal{R})$, where $m \preceq \mathcal{R} \preceq M$. For every $x \in W^u$, and every $z \in \mathcal{R}$ such that $m \preceq z$, there exists $m \in \mathbb{N}$ such that $T^m(x) \preceq_z z$, and for every $x \in W^u$, and every $z \in \mathcal{R}$ such that $z \preceq \mathcal{R}$, there exists $m \in \mathbb{N}$ such that $M \preceq_z T^m(x)$. 

3. Global Dynamics of System (2)
(See Figure 1)

The equilibrium point \( E(\bar{x}, \bar{y}) \) of System (2) satisfies the following system of equations:

\[
\begin{align*}
\bar{x} &= \frac{y_1 \bar{y}}{B_1 \bar{x} + \bar{y}}, \\
\bar{y} &= \frac{\beta_2 \bar{x}}{B_2 \bar{x} + \bar{y}}.
\end{align*}
\] (12)

It is easy to see that System (12) has unique equilibrium point \( E \) in the first quadrant, for all values of the parameters. Indeed, the positive equilibrium point is an intersection of the following two curves:

\[
\begin{align*}
y &= \frac{B_1 x^2}{y_1 - x}, \quad (13) \\
x &= \frac{y^2}{\beta_2 - B_2 y}. \quad (14)
\end{align*}
\]

It is clear that at the point of intersection \( E \) curve (13) is steeper than curve (14), that is,

\[
\left. \frac{dy}{dx} \right|_{(13)}(E) > \left. \frac{dy}{dx} \right|_{(14)}(E),
\] (15)

which gives

\[
\frac{B_2 \bar{x}}{y_1 - \bar{x}} > \frac{(\beta_2 - B_2 \bar{y})^2}{\bar{y}(2\beta_2 - B_2 \bar{y})}.
\] (16)

This inequality is equivalent to the following inequality:

\[
\left( \beta_2 + \frac{\bar{y}^2}{\bar{x}} \right) \left( y_1 + B_1 \frac{\bar{x}^2}{\bar{y}} \right) > B_1 \bar{x} \bar{y},
\] (17)

which is always satisfied.

3.1. Linearized Stability Analysis of System (2).
In this section we present the linearized stability analysis of the equilibrium \( E \) of System (2).

**Theorem 9.** (i) If \( B_1 < B_2 \), then \( E \) is locally asymptotically stable.
(ii) If \( B_1 = B_2 \), then \( E \) is a nonhyperbolic equilibrium point.
(iii) If \( B_1 > B_2 \), then \( E \) is a saddle point.

**Proof.** The map \( T \) associated to System (2) is

\[
T(x, y) = \left( \frac{f(x, y)}{g(x, y)} \right) = \left( \frac{y_1 y}{\beta_2 x + y}, \frac{B_1 y_1}{B_2 x + y} \right).
\] (18)

The Jacobian matrix of map (18) is

\[
J_T(x, y) = \left( \frac{-B_1 y_1 x}{(B_1 x + y)^2} - \frac{B_1 y_1 x}{(B_2 x + y)^2}, \frac{B_1 y_1 x}{(B_1 x + y)^2} - \frac{B_1 y_1 x}{(B_2 x + y)^2} \right),
\] (19)

and evaluated at the equilibrium point \( E = (\bar{x}, \bar{y}) \) is

\[
J_T(\bar{x}, \bar{y}) = \left( \frac{-B_1 \bar{x}^2}{y_1 \bar{y}} - \frac{B_1 \bar{x}^2}{1 \bar{y}}, \frac{\bar{y}^3}{\beta_2 \bar{x}^2} - \frac{\bar{y}^3}{\beta_2 \bar{x}} \right).
\] (20)

The characteristic equation has the following form:

\[
\lambda^2 + \left( \frac{B_1 \bar{x}^2}{y_1 \bar{y}} + \frac{1 \bar{y}^2}{\beta_2 \bar{x}} \right) \lambda = 0,
\] (21)

and the characteristic roots are

\[
\lambda_1 = 0, \quad \lambda_2 = -\frac{B_1 \bar{x}^2}{y_1 \bar{y}} - \frac{1 \bar{y}^2}{\beta_2 \bar{x}}.
\] (22)
A straightforward calculation shows that the conditions \( \lambda_2 \in (-1, 0) \), \( \lambda_2 = -1 \), and \( \lambda_2 \in (-\infty, -1) \), respectively, are equivalent to the conditions

\[
\left( \frac{x}{y} \right)^2 < \frac{\beta_2}{\gamma_1}, \quad \left( \frac{x}{y} \right)^2 = \frac{\beta_2}{\gamma_1}, \quad \left( \frac{x}{y} \right)^2 > \frac{\beta_2}{\gamma_1}. \tag{23}
\]

On the other hand, by dividing two equilibrium equations (12) we obtain

\[
\left( \frac{x}{y} \right)^2 = \frac{\beta_2 B_1 x + y}{\gamma_1 B_2 x + y}, \quad (24)
\]

which implies that the condition (23) is equivalent to the conditions

\[
B_1 < B_2, \quad B_1 = B_2, \quad B_1 > B_2, \tag{25}
\]

which completes the proof of the theorem. \( \square \)

3.2. Global Results for System (2). In this section we present the proof of Theorem 1 on the global dynamics of System (2).

First, we prove the following result on existence and local behavior of the period-two solutions.

**Lemma 10.** System (2) has the minimal period-two solution

\[
\{P_1, P_2\} = \left\{ \left( y_1, 0 \right), \left( 0, \frac{\beta_2}{B_2} \right) \right\} \tag{26}
\]

for all values of parameters. If \( B_1 \neq B_2 \), then the solution (26) is the unique period-two solution and when \( B_1 = B_2 \) there are infinitely many period-two solutions. The set

\[
\mathcal{B} = \{(x, y) \mid x > 0, \quad y = 0 \text{ or } x = 0, \quad y > 0\} \tag{27}
\]

is a subset of the basin of attraction of the solution (26). The period-two solution (26) is locally stable if \( B_1 > B_2 \) and a saddle point if \( B_1 < B_2 \). Finally the period-two solution (26) is nonhyperbolic if \( B_1 = B_2 \).

**Proof.** The second iterate of the map \( T \) is given as

\[
T^2 (x, y) = \left[ \begin{array}{c} y + xB_1 \\ x\beta_2 y_1 + \gamma_1 y B_1 + x y \beta_1 B_2 + \gamma_1 y B_1 B_2 \end{array} \right]. \tag{28}
\]

A period-two solution of System (2) satisfies \( T^2(x, y) = (x, y) \), which immediately leads to the following equations:

\[
(B_2 - B_1) \left( \beta_2 y_1 x - B_2 y_1 x y - \gamma_1 y^2 \right) = 0, \quad (29)
\]

\[
(B_2 - B_1) \left( \beta_2 y_1 y - B_2 x y - \gamma_1 B_1 x^2 \right) = 0. \tag{30}
\]

The Jacobian matrix of \( T^2 \) evaluated at \( P_1 \) is

\[
I_{T^2} (P_1) = \left[ \begin{array}{cc} 0 & -\frac{1}{\beta_2} y_1 B_2 \\ \frac{1}{B_1} B_2 & 0 \end{array} \right]. \tag{32}
\]

\[
I_{T^2} (P_2) = \left[ \begin{array}{cc} \frac{1}{B_1} B_2 & 0 \\ B_2 - \frac{1}{\beta_2 y_1} \left( \frac{\beta_2^2}{B_2} + \beta_2 y_1 B_2 \right) & 0 \end{array} \right]. \tag{33}
\]

The Jacobian matrix of \( T^2 \) evaluated at \( P_2 \) is

\[
I_{T^2} (P_2) = \left[ \begin{array}{c} \frac{1}{B_1} B_2 \\ B_2 - \frac{1}{\beta_2 y_1} \left( \frac{\beta_2^2}{B_2} + \beta_2 y_1 B_2 \right) \end{array} \right]. \tag{31}
\]

and the Jacobian matrix of \( T^2 \) evaluated at \( P_2 \) is

\[
I_{T^2} (P_2) = \left[ \begin{array}{cc} \frac{1}{B_1} B_2 & 0 \\ B_2 - \frac{1}{\beta_2 y_1} \left( \frac{\beta_2^2}{B_2} + \beta_2 y_1 B_2 \right) & 0 \end{array} \right]. \tag{33}
\]
In both cases, the eigenvalues of the Jacobian matrix of $T^2$ are
\[ \lambda_1 = 0, \lambda_2 = B_2/B_1, \]
which implies the result on local stability of the minimal period-two solution \{P_1, P_2\}. \hfill \Box

**Proof of Theorem 1.** First, observe that the rectangle \( R = [0, y_1] \times [0, B_2/B_1] \setminus \{0, 0\} = \{P_2, P_1\} \setminus \{0, 0\} \) is an invariant and attracting set for the map \( T^2 \) and so is for the map \( T^3 \). More precisely, \((x_n, y_n) \in R\) for \( n \geq 1 \). The map \( T^2 \) is a competitive map on \( R \). \hfill \Box

**Case a.** Assume that \( B_1 < B_2 \). Then in view of Theorem 9 and Lemma 10, the map \( T^2 \) has three equilibrium points \( P_1, P_2, \) and \( E \), where \( P_2 \leq_E E \leq_P P_1 \), \( \lambda_1 = 0 \), \( \lambda_2 = B_2/B_1 \), \( E \) is a saddle point and \( P_1 \) is a local attractor. The ordered intervals \([P_2, E] \) and \([E, P_1] \) are both invariant sets of \( T^2 \) and in view of Corollary 6, their interiors are attracted to \( E \). If we take the point \((x, y) \in R \setminus [P_2, E] \cup [E, P_1]\), we can find the points \((x, y) \in \text{int} [P_2, E] \) and \((x, y) \in \text{int} [E, P_1] \), such that \((x_1, y_1) \leq_E (x, y) \leq_E (x_n, y_n) \). Consequently, since \( T^2 \) is competitive \( T^{2n}((x, y)) \leq_E T^{2n}((x, y)) \leq_E T^{2n}((x_n, y_n)) \) for \( n \geq 1 \) and so \( \lim_{n \to \infty} T^{2n}((x, y)) = E \), which by continuity of \( T \) implies that

\[
\lim_{n \to \infty} T^{2n-1}((x, y)) = \text{int} T\left( T^{2n}((x, y)) \right) = T\left( \lim_{n \to \infty} T^{2n}((x, y)) \right) = T(E) = E,
\]

and so \( \lim_{n \to \infty} T^n((x, y)) = E \).

**Case b.** Assume that \( B_1 > B_2 \). Then in view of Theorem 9 and Lemma 10, the map \( T^3 \) has three equilibrium points \( P_1, P_2, \) and \( E \) which are local attractors and \( E \) is a saddle point. The ordered intervals \([P_2, E] \) and \([E, P_1] \) are both invariant sets for \( T^2 \) and in view of Corollary 6, their interiors are attracted to \( P_1 \) and \( P_2 \), respectively. In view of Theorems 7 and 8, there is the set \( C \) with described properties. Direct calculation shows that the half-line \( y = \sqrt{\varphi(x), x > 0} \) is an invariant set which in view of a uniqueness of stable manifold implies that this half-line is exactly stable manifold mentioned in Theorems 7 and 8. It should be observed that because of the fact that one of the characteristic values at the equilibrium point \( E \) is \( 0 \), this equilibrium is superattractive, that is, \( T(x_0, y_0) = (\varphi, \psi) \), for every \((x_0, y_0) \in C\).

**Case c.** Assume that \( B_1 = B_2 \). Then by dividing two equations of System (2) we obtain that the solution of (2) satisfies

\[
\frac{y_{n+1}}{x_{n+1}} = \frac{y_2}{\beta_1 y_n} x_n = \frac{1}{\beta_1 y_n} x_n.
\]

Thus \( y_n/x_n \) satisfies first order difference equation \( u_{n+1} = D/u_n \) where \( D = y_2/\beta_1 \). All nonconstant solutions of \( u_n \) are period-two solutions \{\( u_0, D/u_0 \).\}

Thus \( y_n = \{u_0 x_n, (D/u_0)x_n\} \). In this case, System (2) becomes

\[
x_{n+1} = \frac{B_1 u_0}{B_1 + u_0}, \quad y_{n+1} = \frac{\beta_2}{B_1 + u_0}, \quad n = 1, 2, \ldots \quad (36)
\]

\[
x_{n+1} = \frac{B_1 D}{D + B_1 u_0}, \quad y_{n+1} = \frac{\beta_1 u_0}{D + B_1 u_0}, \quad n = 1, 2, \ldots
\]

which completes the proof of Case (c).

**Remark 1.** System (2) is an example of the homogeneous system which is a special case of a general System (1), where both functions \( f \) and \( g \) are homogeneous functions of the same degree \( k \), that is,

\[
f(tu, tv) = t^k f(u, v), \quad g(tu, tv) = t^k g(u, v)
\]

for all \( u, v \) in intersection of domains of \( f \) and \( g \) and all \( t \neq 0 \). In that case, the ratio \( z_n = y_n/x_n \) of every solution of (1) satisfies the first order difference equation:

\[
z_{n+1} = f(1, z_n)/g(1, z_n) = F(z_n), \quad n = 0, 1, \ldots \quad (37)
\]

whence analysis gains valuable information about the dynamics of System (1), but does not provide the global dynamics. In particular, this approach cannot determine precisely the basins of attraction of different types of attractors such as equilibrium points and periodic solutions. This approach in the case of the system of linear fractional equations:

\[
x_{n+1} = \frac{\alpha_1 + \beta_1 x_n + \gamma_1 y_n}{A_1 + B_1 x_n + C_1 y_n}, \quad y_{n+1} = \frac{\alpha_2 + \beta_2 x_n + \gamma_2 y_n}{A_2 + B_2 x_n + C_2 y_n}, \quad n = 0, 1, \ldots \quad (38)
\]

where all parameters and the initial conditions \((x_0, y_0)\) are arbitrary nonnegative numbers such that \( A_i + B_i x_0 + C_i y_0 > 0, \quad i = 1, 2, \) was first used in [19] and was systematically developed in the recent paper [20]. In [20], the authors studied all possible homogeneous systems of the form (38) and they proved that every bounded solution converges to either an equilibrium solution or to period-two solution. They were able to find a part of the basin of attraction of the period-two solution but not the complete basin of attraction. In the case of system (2) the auxiliary equation for \( z_n = y_n/x_n \) is

\[
z_{n+1} = \frac{\beta_1 (B_1 + z_n)}{\gamma_1 (B_2 + z_n)} z_n, \quad n = 0, 1, \ldots \quad (39)
\]

Since \( F \) is decreasing, every solution of the auxiliary equation is approaching not necessarily minimal period-two solution. Further analysis can be continued either by checking negative feedback condition for \( F^2 \) or by using Theorem 3.2 from [20]. In neither case the complete description of the basins of attraction of the equilibrium and the period-two solution is possible. We prefer our approach because it is more precise and also apply equally well to anticompetitive systems which are not homogeneous. The approach which is making use of homogeneous properties of functions is applicable also to the systems which are neither competitive nor anticompetitive.
4. Global Dynamics of System (3) (See Figure 2)

The equilibrium point $E(\overline{x}, \overline{y})$ of System (3) satisfies the following system of equations:

$$\overline{x} = \frac{\gamma_1 \overline{y}}{B_1 \overline{x} + \overline{y}}, \quad \overline{y} = \frac{\alpha_2 + \beta_2 \overline{x}}{\beta_2}.$$  (40)

It is easy to see that System (40) has the unique equilibrium point $E$ in the first quadrant, for all values of the parameters. Indeed, the positive equilibrium point is an intersection of the following two curves:

$$y = \frac{B_1 \overline{x}^2}{\gamma_1 - \overline{x}},$$  (41)

$$x = \frac{y^2 - \alpha_2}{\beta_2}.$$  (42)

It is clear that at the point of intersection $E$ curve (41) is steeper than curve (42), that is,

$$\left.\frac{dy}{dx}\right|_{(41)}(E) > \left.\frac{dy}{dx}\right|_{(42)}(E),$$  (43)

which gives

$$\frac{B_1 \overline{x}(2\gamma_1 - \overline{x})}{(\gamma_1 - \overline{x})^2} > \frac{\beta_2}{\beta_2}.$$  (44)

This inequality is equivalent to the following inequality:

$$2\beta_1 \overline{x}(2\gamma_1 - \overline{x}) > \beta_2 (\gamma_1 - \overline{x})^2,$$  (45)

which in turn is equivalent to

$$2 + \frac{2 \gamma_1 \overline{x}^2}{\gamma_1 \overline{y}} > \frac{\beta_2 \gamma_1 \overline{x}^3}{\gamma_1 \overline{y}}.$$  (46)

4.1. Linearized Stability Analysis of System (3). In this section we prove the following result.

Theorem 12. The unique equilibrium $E$ of System (3) is a saddle point.

Proof. The map $S$ associated to System (3) is

$$S(x, y) = \left(\frac{f(x, y)}{g(x, y)}\right) = \left(\frac{\gamma_1 y}{B_1 x + y}, \frac{\alpha_2 + \beta_2 x}{\gamma_1 \overline{y}}\right).$$  (47)

The Jacobian matrix of map (47) is

$$J_S(x, y) = \begin{pmatrix} - \frac{B_1 \gamma_1 y}{(B_1 x + y)^2} & \frac{B_1 \gamma_1 x}{(B_1 x + y)^2} \\ \frac{\beta_2}{\gamma_1 \overline{y}} & - \frac{\alpha_2 + \beta_2 x}{\gamma_1 \overline{y}} \end{pmatrix}.$$  (48)

and evaluated at the equilibrium point $E = (\overline{x}, \overline{y})$ is

$$J_S(\overline{x}, \overline{y}) = \begin{pmatrix} - \frac{B_1 \gamma_1 \overline{x}}{\gamma_1 \overline{y}} & \frac{B_1 \gamma_1 \overline{x}}{\gamma_1 \overline{y}} \\ \frac{\beta_2}{\gamma_1 \overline{y}} & -1 \end{pmatrix}.$$  (49)

The characteristic equation has the following form:

$$\lambda^2 + \left(1 + \frac{B_1 \overline{x}}{\gamma_1 \overline{y}}\right)\lambda + \frac{B_1 \overline{x}^2}{\gamma_1 \overline{y}^2} = 0.$$  (50)

Set

$$P = 1 + \frac{B_1 \overline{x}}{\gamma_1 \overline{y}}, \quad Q = \frac{B_1 \overline{x}^2}{\gamma_1 \overline{y}^2} - \beta_2 \frac{B_1 \overline{x}^3}{\gamma_1 \overline{y}^3}.$$  (51)

Then the necessary and sufficient condition for (50) to have one root inside the unit circle and one root outside the unit circle is $|P| > |1 + Q|$, $P^2 - 4Q > 0$; see [7, 21]. The condition $|P| > |1 + Q|$ leads to $P > 1 - Q$ which is equivalent to

$$2 + 2 \frac{B_1 \overline{x}^2}{\gamma_1 \overline{y}} > \beta_2 \frac{B_1 \overline{x}^3}{\gamma_1 \overline{y}^2},$$  (52)

which is condition (46). The condition $P^2 - 4Q > 0$ becomes

$$\left(1 + \frac{B_1 \overline{x}}{\gamma_1 \overline{y}}\right)^2 - 4 \left(\frac{B_1 \overline{x}^2}{\gamma_1 \overline{y}^2} - \beta_2 \frac{B_1 \overline{x}^3}{\gamma_1 \overline{y}^3}\right) > 0,$$  (53)

which is equivalent to

$$\left(1 - \frac{B_1 \overline{x}}{\gamma_1 \overline{y}}\right)^2 + 4\beta_2 \frac{B_1 \overline{x}^3}{\gamma_1 \overline{y}^3} > 0,$$  (54)

which is clearly satisfied. □
4.2. Global Results for System (3)

Lemma 13. System (3) has no minimal period-two solution.

Proof. The second iterate of the map $S$ is given as

$$S^2(x, y) = \left( y_1 \left( y + x B_1 \right) \frac{\alpha_2 + x B_2}{\beta_2 B_1 y^2 + \beta_2 x y + \alpha_2 B_1 x + y_1 B_1 y^2 + \alpha_2 y} , \frac{y}{\beta_2 B_1 x^2 + \beta_2 x y + \alpha_2 B_1 x + y_1 B_1 y^2 + \alpha_2 y} \right). \tag{55}$$

Period-two solution satisfies $S^2(x, y) = (x, y)$ which reduces to the following two equations:

$$\gamma_1 \left( y + x B_1 \right) \left( \alpha_2 + x B_2 \right) - x \left( \beta_2 B_1 x^2 + \beta_2 x y + \alpha_2 B_1 x + y_1 B_1 y^2 + \alpha_2 y \right) = 0, \tag{56}$$

$$y_2 \left( \alpha_2 + x B_2 \right) y_1 - x \left( \alpha_2 + x B_2 \right) \left( \alpha_2 + x B_2 \right) = 0. \tag{57}$$

Equation (57) leads immediately to $y_1 = x - x^2 B_1 = 0$ which is exactly the equilibrium equation (41). Using (41) in (56), we obtain after some elementary simplification that period-two solution satisfies (42). This shows that System (3) has no minimal period-two solution.

Lemma 14. The maps $S$ and $S^2$ associated with System (3) have the following properties.

(i) The maps $S$ and $S^2$ are injective.

(ii) $\det J_S(x, y) > 0$ for all $(x, y), y > 0$.

Consequently, $S^2$ satisfies $(O+) \text{ condition and so } \{S^{2n}(x_0, y_0)\}$ is eventually componentwise monotone.

Proof. (i) We will prove that $S$ is injective and the injectivity of $S^2$ will follow immediately. The condition

$$S(x_1, y_1) = S(x_2, y_2) \tag{58}$$

is reduced to the following two conditions:

$$x_2 y_1 = x_1 y_2, \quad \alpha_2 \left( y_2 - y_1 \right) = \beta_2 \left( x_2 y_1 - x_1 y_2 \right), \tag{59}$$

which immediately implies $y_1 = y_2$ and so $x_1 = x_2$.

(ii) A direct calculation shows that

$$\det J_S = \frac{B_2^2 \alpha_2^2 y_1^2 + y_2^2 - \left( \alpha_2 + x B_2 \right) \left( \alpha_2 + x B_2 \right) y_1^2}{\left( \alpha_2 + x B_2 \right) \left( \alpha_2 + x B_2 \right) \left( \alpha_2 + x B_2 \right) \left( \alpha_2 + x B_2 \right) \left( \alpha_2 + x B_2 \right) \left( \alpha_2 + x B_2 \right)} \tag{60}$$

which implies our statement.

The statement on $(O+) \text{ condition follows from Theorem 5.}$

Theorem 15. Consider System (3). Then there exists a set $C \subseteq \mathbb{D} = [0, \infty) \times (0, \infty)$ which is invariant subset of the basin of attraction of $E$. The set $C$ is a graph of a strictly increasing continuous function of the first variable on an interval and separates $\mathbb{D}$ into two connected and invariant components, namely,

$$\mathcal{W}_- := \{ x \in \mathbb{D} \setminus C : \exists y \in C \text{ with } x \leq_{sc} y \}, \tag{61}$$

$$\mathcal{W}_+ := \{ x \in \mathbb{D} \setminus C : \exists y \in C \text{ with } y \leq_{sc} x \}, \tag{62}$$

which satisfy the following.

(i) If $(x_0, y_0) \in \mathcal{W}_+$, then

$$\lim_{n \to \infty} (x_{2n}, y_{2n}) = E, \quad \lim_{n \to \infty} (x_{2n+1}, y_{2n+1}) = (0, \infty). \tag{63}$$

(ii) If $(x_0, y_0) \in \mathcal{W}_-$,

$$\lim_{n \to \infty} (x_{2n}, y_{2n}) = (0, \infty), \quad \lim_{n \to \infty} (x_{2n+1}, y_{2n+1}) = E. \tag{64}$$

Proof. Clearly, the rectangle $[0, 1] \times (0, \infty)$ is an invariant and attracting set for the map $S$. In particular, $x_n \leq y$ for $n \geq 1$.

Then by Lemma 14 and Theorem 4, every solution $(x_n, y_n)$ of System (3) has eventually monotone components \{$(x_{2n}, y_{2n})$\} and \{$(x_{2n+1}, y_{2n+1})$\}, which shows that every bounded solution converges to period-two solution. In view of Lemma 13, there are no minimal period-two solutions and so every bounded solution of System (3) converges to the equilibrium $E$. In view of Theorems 7 and 8, there is a set $C$ with described properties. Consequently, every solution with an initial point $(x_0, y_0) \in \mathcal{W}_+$ converges to $E$, while every solution which starts in $\mathcal{W}_-$ approaches $(0, \infty)$ and is asymptotic to the global unstable manifold $W^u(E)$. 

5. Global Dynamics of System (4)

(See Figure 3)

The equilibrium point $E(x, y)$ of System (4) satisfies the following system of equations:

$$x = \frac{y_1 y}{A_1 + \bar{x}}, \quad y = \frac{\alpha_2 + \beta_2 \bar{x}}{y}. \tag{64}$$

It is easy to see that System (64) has the unique equilibrium point $E$ in the first quadrant, which is an intersection of two parabolas:

$$y = \frac{x(B_1 + x)}{y_1}, \tag{65}$$

$$x = \frac{y^2 - \alpha_2}{\beta_2}. \tag{66}$$

It is clear that at the point of intersection $E$, curve (65) is steeper than curve (66), that is,

$$\frac{dy}{dx} \bigg|_{(65)} (E) > \frac{dy}{dx} \bigg|_{(66)} (E), \tag{67}$$

which gives

$$2\bar{y} \left( A_1 + 2\bar{x} \right) > \beta_2 y_1. \tag{68}$$
5.1. Linearized Stability Analysis of System (4). In this section we prove the following result.

Theorem 16. The unique equilibrium \( E \) of System (4) is a saddle point.

Proof. The map \( S \) associated to System (4) is

\[
U(x, y) = \left( \frac{y_1 y}{A_1 + x}, \frac{\alpha_2 + \beta_2 x}{y} \right).
\]

(69)

The Jacobian matrix of map (69) has the form:

\[
J_U(x, y) = \begin{pmatrix}
-\frac{y_1 y}{(A_1 + x)^2} & \frac{y_1}{A_1 + x} \\
\beta_2 & -\frac{\alpha_2 + \beta_2 x}{y^2} \\
\end{pmatrix},
\]

(70)

which evaluated at the equilibrium point \( E = (\bar{x}, \bar{y}) \) is

\[
J_U(\bar{x}, \bar{y}) = \begin{pmatrix}
-\frac{\bar{x}}{A_1 + \bar{x}} & \frac{y_1}{A_1 + \bar{x}} \\
\beta_2 & -1 \\
\end{pmatrix}.
\]

(71)

The characteristic equation of System (4) has the following form:

\[
\lambda^2 + \left(1 + \frac{\bar{x}}{A_1 + \bar{x}}\right) \lambda + \frac{\bar{x}}{A_1 + \bar{x}} - \frac{\beta_2 y_1}{\bar{y}(A_1 + \bar{x})} = 0.
\]

(72)

Set

\[
P = 1 + \frac{\bar{x}}{A_1 + \bar{x}}, \quad Q = \frac{\bar{x}}{A_1 + \bar{x}} - \frac{\beta_2 y_1}{\bar{y}(A_1 + \bar{x})}.
\]

(73)

is \( |P| > 1 + Q, \) \( P^2 - 4Q > 0 \); see [7, 21]. In view of the fact that \( P > 1 + Q, \) the condition \( |P| > 1 + Q \) leads to \( P > -1 - Q \) which is equivalent to

\[
2 + 2 \frac{\bar{x}}{A_1 + \bar{x}} > \frac{\beta_2 y_1}{\bar{y}(A_1 + \bar{x})},
\]

(74)

which is equivalent to the condition (68).

The condition \( P^2 - 4Q > 0 \) becomes

\[
\left(1 - \frac{\bar{x}}{A_1 + \bar{x}}\right)^2 + 4 \frac{\beta_2 y_1}{\bar{y}(A_1 + \bar{x})} > 0,
\]

(75)

which is clearly satisfied.

5.2. Global Results for System (4)

Lemma 17. System (4) has no minimal period-two solution.

Proof. The second iterate of the map \( U \) is given as

\[
U^2(x, y) = \left( \frac{y_1 y}{A_1 + x + A_1}, \frac{\alpha_2 + x \beta_2}{A_1 + x A_1 + y A_1 y_1}, \frac{y y_1}{(x + A_1) (\alpha_2 + x \beta_2)} \left(\alpha_2 + \alpha_2 A_1 + y \beta_2 y_1\right)\right).
\]

(77)

Period-two solution satisfies \( U^2(x, y) = (x, y) \) which reduces to the following two equations:

\[
xy (A_1 x + y) = y_1 (\alpha_2 + \beta_2 x),
\]

(78)

\[
y_1 y = x (A_1 + x).
\]

(79)

Equation (79) is exactly the equilibrium equation (65). Using (65) in (78) we obtain after some elementary simplification that period-two solution satisfies (66). This shows that System (4) has no minimal period-two solution. □

Lemma 18. The maps \( U \) and \( U^2 \) associated with System (4) have the following properties.

(i) If \( A_1 \beta_2 \neq \alpha_2 \), then the maps \( U \) and \( U^2 \) are injective.

(ii) If \( A_1 \beta_2 \neq \alpha_2 \), then \( \det J_U(x, y) > 0 \) for all \( (x, y), y > 0 \).

Consequently, \( U^2 \) satisfies \((O+)\) condition, when \( A_1 \beta_2 \neq \alpha_2 \).

Proof. (i) We will prove that \( U \) is injective which will imply the injectivity of \( U^2 \). The condition

\[
U(x_1, y_1) = U(x_2, y_2)
\]

(80)
Discrete Dynamics in Nature and Society

is reduced to the following two conditions:
\[ A_1(y_2 - y_1) = x_2y_1 - x_1y_2, \]
\[ \alpha_2(y_2 - y_1) = \beta_2(x_2y_1 - x_1y_2), \]  
which implies that \( y_2 - y_1 = (1/A_1)(x_2y_1 - x_1y_2) = (\beta_2/\alpha_2)(x_2y_1 - x_1y_2) \)
\[ \left(1 - \frac{\beta_2}{A_1}\right)(x_2y_1 - x_1y_2) = 0, \]  
and \( x_2y_1 - x_1y_2 = 0 \) when \( A_1\beta_2 \neq \alpha_2 \). This implies \( y_1 = y_2 \) and so \( x_1 = x_2 \).

(ii) A direct calculation shows that
\[ \det J_{I_{\alpha_2}} = (\alpha_2 - A_1\beta_2)^2 \frac{y_1}{(\alpha_2 + \beta_2x)(\alpha_1^2 + A_1x + y_1y_2)^2}, \]
which proves our statement.

The statement on \((O+\) condition follows from Theorem 5.

Theorem 19. Consider System (4). Assume that \( A_1\beta_2 \neq \alpha_2 \). Then there exists a set \( C \subset \mathcal{D} = [0, \infty) \times (0, \infty) \) which is invariant subset of the basin of attraction of \( E \). The set \( C \) is a graph of a strictly increasing continuous function of the first variable on an interval and separates \( \mathcal{D} \) into two connected and invariant components, namely,
\[ \mathcal{W}_- := \{x \in \mathcal{D} : \exists y \in C \text{ with } x \leq_{se} y \}, \]
\[ \mathcal{W}_+ := \{x \in \mathcal{D} : \exists y \in C \text{ with } y \leq_{se} x \}, \]
which satisfy the following.
(i) If \((x_0, y_0) \in \mathcal{W}_+\), then
\[ \lim_{n \to \infty} (x_{2n}, y_{2n}) = (\infty, 0), \quad \lim_{n \to \infty} (x_{2n+1}, y_{2n+1}) = (0, \infty), \]  
(ii) If \((x_0, y_0) \in \mathcal{W}_-\), then
\[ \lim_{n \to \infty} (x_{2n}, y_{2n}) = (0, 0), \quad \lim_{n \to \infty} (x_{2n+1}, y_{2n+1}) = (0, \infty). \]

Proof. Assume that \( A_1\beta_2 \neq \alpha_2 \). Then by Lemma 18 and Theorem 4, every solution \( \{x_n, y_n\} \) of System (4) has eventually monotone components \( \{x_{2n}, y_{2n}\} \) and \( \{x_{2n+1}, y_{2n+1}\} \), which shows that every bounded solution converges to a period-two solution. In view of Lemma 17, there are no minimal period-two solutions and so every bounded solution of System (4) converges to the equilibrium \( E \). In view of Theorems 7 and 8, there is a set \( C \) with described properties. Consequently, the regions \( \mathcal{W}_- \) and \( \mathcal{W}_+ \) are invariant for \( U_2 \) and every solution in \( \mathcal{W}_-(\mathcal{W}_+) \) is asymptotic to the unstable manifold \( \mathcal{W}^u(E) \) and so the statement of the theorem follows.

Theorem 20. Consider System (4). Assume that \( A_1\beta_2 = \alpha_2 \). Then System (4) can be decoupled and written as
\[ x_{n+1} = \frac{\beta_2y_1^2}{x_n(A_1 + x_n)}, \quad y_{n+1} = \beta_2y_1 + \frac{A_1y_n}{y_n^2}, \]  
\[ n = 0, 1, \ldots. \]

Every solution \( \{x_n, y_n\} \) of System (87) has eventually monotone subsequences \( \{x_{2n}, y_{2n}\} \) and \( \{x_{2n+1}, y_{2n+1}\} \). Every bounded solution converges to the unique positive equilibrium. Every unbounded solution \( \{x_n, y_n\} \) approaches either \((0, 0)\) or \((0, \infty)\).

Proof. Using the condition \( A_1\beta_2 = \alpha_2 \) in the second equation of System (4) gives
\[ y_{n+1} = \beta_2x_n + \frac{A_1}{y_n^2}, \]
and so \( x_{n+1}y_{n+1} = \beta_2y_1 \) which shows that System (4) has an invariant of the form:
\[ x_ny_n = \beta_2y_1, \quad n = 1, 2, \ldots. \]
Using (89), System (4) is reduced to System (87). Both equations of System (87) are first order difference equations with decreasing functions and so by Theorem 1.19 [7], the subsequences of even and odd indexes are eventually monotonic and so every bounded solution converges to a period-two solution. An immediate checking shows that neither one of the two equations of System (87) has period-two solutions. For example, the unique equilibrium \( \bar{x} \) of the first equation of System (87) satisfies
\[ x^3 + A_1x^2 - \beta_2y_1^2 = 0, \]
while period-two solution satisfies \( f^2(x) = x \) which becomes \( x^3((A + x)^2/(A^2 + Ax + C)) = x \) and so is reduced to (90). Thus every bounded solution converges to the unique equilibrium.

The result for unbounded solutions follows immediately from (89).

Acknowledgment

The authors are grateful to one of the anonymous referees for pointing out the equation of the stable manifold for (2) and for observing the alternative method of the proof of Theorem 1 mentioned in Remark II.
