Nonperiodic flow in the numerical integration of a nonlinear differential equation of fluid dynamics

Edmund X. DeJesus and Charles Kaufman
Department of Physics, University of Rhode Island, Kingston, Rhode Island 02881
(Received 20 April 1984)

Viscous incompressible fluid flow along a flat plate is modeled by the Navier-Stokes equations with appropriate boundary conditions. A series solution is assumed and a set of three nonlinear ordinary differential equations is derived by truncating the series. The Reynolds number appears in these three equations as a parameter. These equations are solved by numerical integration. We show that these solutions exhibit qualitatively different behavior for different values of the Reynolds number of the fluid. The various modes include an asymptotic approach to a time-independent state, laminar (periodic) flow, and turbulence. We give several computer-generated pictures of the various modes.

I. INTRODUCTION

The Orr-Sommerfeld equation provides the classic route for the determination of boundary layer stability of fluid flow along a flat plate. More recently, chaotic solutions to differential equations have become a tantalizing possibility for the mathematical description of turbulent flow. Here we report on some results of calculations which combine aspects of both approaches. We derive a nonlinear partial differential equation to approximate flow along a flat plate. From this equation we determine a set of three ordinary nonlinear differential equations, and demonstrate that solutions to these equations exhibit both regular and chaotic behavior. We present also some details of this behavior.

II. PROCEDURE

A. Derivation of equations

We begin with the Navier-Stokes equation for viscous flow. Written in terms of the vorticity, these are

\[ \frac{\partial \Omega_k}{\partial t} + \frac{\partial \Omega_k}{\partial x_j} = \mu \frac{\partial^2 \Omega_k}{\partial x_i \partial x_j} + \frac{\partial P}{\partial x_j} \delta_{ij} + \rho \Omega_k \frac{\partial U}{\partial x_j} - \rho \Omega_k \theta, \]  

where \( \Omega_k \) is the \( k \)th component of vorticity, \( t \) is time, \( \mu \) is absolute viscosity, \( x_j \) is the \( j \)th space coordinate, \( U_k \) is the \( k \)th component of the flow velocity, \( \theta \) is the divergence of the flow velocity, and \( k \) is 1,2,3.

We assume the fluid incompressible, so that the second term on the right-hand side of (1) is zero; also, \( \theta \), the divergence of the flow velocity, is zero and the fourth term on the right-hand side of (1) is zero. We retain

\[ \frac{\partial \Omega_k}{\partial t} = \frac{\partial^2 \Omega_k}{\partial x_i \partial x_j} + \rho \Omega_k \frac{\partial U}{\partial x_j}, \]  

and

\[ \frac{\partial U}{\partial x_j} = \rho \frac{\partial \Omega_k}{\partial x_k}, \]  

where

\[ \omega = \frac{\partial U_1}{\partial x_2} - \frac{\partial U_2}{\partial x_1} \]  

With \( \Omega_3 \) from Eq. (5), \( \Omega_3 = 0 \), and with some rearrangement, Eq. (4) is

\[ \rho \frac{D \Omega_3}{Dt} = \mu \frac{\partial^2 \Omega_3}{\partial x_i \partial x_j} + \rho \Omega_1 \frac{\partial U_3}{\partial x_i} + \rho \Omega_2 \frac{\partial U_3}{\partial x_i}. \]  

We further assume the flow field \( U_k \) to be a basic flow, \( U(x,t) \), with a perturbation of \( u_1(x_1,x_2,t) \) and \( u_2(x_1,x_2,t) \), i.e.,

\[ \begin{align*}
U_1 &= U_1 + u_1, \\
U_2 &= u_2, \\
U_3 &= 0.
\end{align*} \]

Consider Eq. (2) with \( k = 3 \):

\[ \rho \frac{D \Omega_3}{Dt} = \frac{\partial^2 \Omega_3}{\partial x_i \partial x_j} + \rho \Omega_1 \frac{\partial U_3}{\partial x_i} + \rho \Omega_2 \frac{\partial U_3}{\partial x_i}. \]  

Using Eq. (3c), \( U_3 = 0 \) and the second term on the right-hand side of Eq. (4) is zero. We evaluate \( \Omega_3 \) in terms of the basic flow and perturbative flow as

\[ \begin{align*}
\Omega_3 &= -\epsilon_{ijk} \frac{\partial U_i}{\partial x_j} \\
&= - \frac{\partial (U_1 + u_1)}{\partial x_2} + \frac{\partial u_2}{\partial x_1} \\
&= \frac{\partial u_2}{\partial x_1} - \frac{\partial u_1}{\partial x_2}, \\
\omega_3 &= \frac{\partial U_1}{\partial x_2} - \frac{\partial U_2}{\partial x_1}.
\end{align*} \]

With \( \Omega_3 \) from Eq. (5), \( \Omega_3 = 0 \), and with some rearrangement, Eq. (4) is
\[
\frac{\partial}{\partial t} \left[ (\bar{U}_1 + u_1) \frac{\partial}{\partial x_1} + u_2 \frac{\partial}{\partial x_2} \right] \omega_3 \\
- \left[ \frac{\partial}{\partial t} + (\bar{U}_1 + u_1) \frac{\partial}{\partial x_1} + u_2 \frac{\partial}{\partial x_2} \right] \frac{\partial \bar{U}_1}{\partial x_2} \\
= \frac{\mu}{\rho} \nabla^2 \omega_3 - \frac{\frac{1}{2}}{\rho} \frac{\partial \bar{U}_1}{\partial x_2}. \quad (6)
\]

Recall that \( \bar{U}_1 = \bar{U}_1(x_2) \), so that derivatives of \( \bar{U}_1 \) with respect to \( t \) or \( x_1 \) are zero. We rearrange the resultant equation:

\[
\frac{\partial \omega_3}{\partial t} + \bar{U}_1 \frac{\partial \omega_3}{\partial x_1} + u_1 \frac{\partial \omega_3}{\partial x_1} + u_2 \frac{\partial \omega_3}{\partial x_2} - u_2 \frac{\partial \bar{U}_1}{\partial x_2} \\
= \frac{\mu}{\rho} \nabla^2 \omega_3 - \frac{\frac{1}{2}}{\rho} \frac{\partial \bar{U}_1}{\partial x_2}. \quad (7)
\]

We now introduce a stream function \( \Psi = \Psi(x_1, x_2, t) \) to represent the perturbative terms, such that

\[
\begin{align*}
\omega_1 &= \frac{\partial \Psi}{\partial x_2}, \\
\omega_2 &= -\frac{\partial \Psi}{\partial x_1}, \\
\omega_3 &= -\nabla^2 \Psi. \\
\end{align*} \quad (8a-c)
\]

Using Eqs. (8) in Eq. (7) gives

\[
- \frac{\partial}{\partial t} \nabla^2 \Psi - \bar{U}_1 \frac{\partial}{\partial x_1} \nabla^2 \Psi + \frac{\partial^2 \bar{U}_1}{\partial x_2^2} \frac{\partial \Psi}{\partial x_1} \\
= -\frac{\mu}{\rho} \nabla^2 \Psi + \left[ \frac{\partial \Psi}{\partial x_2} \frac{\partial}{\partial x_1} \nabla^2 \Psi - \frac{\partial \Psi}{\partial x_1} \frac{\partial}{\partial x_2} \nabla^2 \Psi \right] \\
- \frac{\mu}{\rho} \frac{\partial^2 \bar{U}_1}{\partial x_2^2}. \quad (9)
\]

To simplify the form of Eq. (9) we make the following substitutions: \( x \) for \( x_1, y \) for \( x_2, U \) for \( \bar{U}_1, U_{yy} \) for \( \frac{\partial^2 \bar{U}_1}{\partial x_2^2}, U_{y'}, \Psi_x \) for \( \frac{\partial}{\partial x_1}, \Psi_y \) for \( \frac{\partial}{\partial x_2} \). This simplification gives

\[
- \frac{\partial}{\partial t} \nabla^2 \Psi - U \frac{\partial}{\partial x} \nabla^2 \Psi + U_{yy} \Psi_x + \frac{\mu}{\rho} \nabla^2 \Psi \\
+ \left[ \Psi_x \frac{\partial}{\partial y} - \Psi_y \frac{\partial}{\partial x} \right] \nabla^2 \Psi + \frac{\mu}{\rho} U_{y''} = 0. \quad (10)
\]

We wish to render Eq. (10) dimensionless. We make the assumption that flow is restricted (in the \( y \) direction) to a boundary layer of thickness \( \delta \). We further assume that the free-stream velocity is \( U_0 \). With these assumptions we obtain the dimensionless equation

\[
- \frac{\partial}{\partial t} \nabla^2 \Psi + U \frac{\partial}{\partial x} \nabla^2 \Psi + U_{yy} \frac{\partial \Psi}{\partial x} + \frac{1}{R} \nabla^2 \Psi \\
+ \left[ \Psi_x \frac{\partial}{\partial y} - \Psi_y \frac{\partial}{\partial x} \right] \nabla^2 \Psi + \frac{\mu}{\rho} U_{y''} = 0, \quad (11)
\]

where \( R = \frac{\rho \delta U_0 / \mu}{} \) is identified as the Reynolds number. (Note that by neglecting terms nonlinear in \( \Psi \) and assuming \( U_{yy} \) vanishes, Eq. (11) can be truncated. Assuming that \( \Psi \) is of the form \( \Psi = \phi(y) \exp[\alpha(x - ct)] \) in this truncated equation then yields the Orr-Sommerfeld equation. Equation (11) is implicit in the standard derivation of the Orr-Sommerfeld equation, but does not explicitly appear in standard references on the subject.

1. Choosing the stream function \( \Psi \)

It is difficult to choose a stream function, \( \Psi(x, y, t) \), which preserves the nonlinear character of Eq. (11). After examining many possibilities, we have chosen

\[
\Psi = \Psi(x, y, t) = -\frac{A}{\lambda^2} \cos(ly) - \frac{B}{\lambda^2} \cos(kx) \\
- \frac{2C}{\lambda^2 + \lambda^2} \sin(ly) \sin(kx), \quad (12)
\]

where \( A = A(t), B = B(t), C = C(t), \) and \( k, l \) are positive real constants. This choice was suggested by a stream function used by Lorenz in his paper "Maximum Simplification of the Dynamic Equations." Using Eq. (12) in Eq. (11) gives

\[
- \frac{\partial}{\partial t} \nabla^2 \Psi - U \frac{\partial}{\partial x} \nabla^2 \Psi + U_{yy} \Psi_x + \frac{\mu}{\rho} \nabla^2 \Psi \\
+ \left[ \Psi_x \frac{\partial}{\partial y} - \Psi_y \frac{\partial}{\partial x} \right] \nabla^2 \Psi + \frac{\mu}{\rho} U_{y''} = 0. \quad (13)
\]
2. Choosing the flow function \( U \)

The flow function \( U \) is a function of \( y \) only. The boundary conditions of flow along a flat plate suggest that \( U \) should be small for \( y \) near zero. Also, \( U \) should approach \( U_0 \) as \( y \) approaches the boundary layer thickness, \( \delta \). (This latter restriction can be achieved through the use of a multiplicative constant.) These restrictions still allow considerable freedom in choosing \( U \). We chose (and justify our choice in the Appendix)

\[
U_{yy} = \frac{m}{\sin(ly)}.
\]  

(14)

It is our intention to keep only those terms of Eq. (13) that are like the terms appearing in \( \Psi \), Eq. (12), namely, multiples of \( \cos(ly) \), \( \cos(kx) \), and \( \sin(ly) \sin(kx) \). Therefore we make the trigonometric substitutions \( 1 - \sin^2(kx) \) for \( \cos^2(kx) \) and \( 1 - \sin^2(ly) \) for \( \cos^2(ly) \) in Eq. (13). We also substitute Eq. (14) in Eq. (13), noting that \( U \) and \( U_{yy} \) will give rise to terms that will not be kept. The resulting equation is

\[
\begin{align*}
\cos(ly) \left[ -\dot{A} \frac{l^2}{R} A + BC \frac{2l^3}{k(k^2+l^2)} \right] + \cos(kx) \left[ -\dot{B} \frac{k^2}{R} B + AC \frac{-2k^3}{l(k^2+l^2)} \right] \\
+ \sin(ly) \sin(kx) \left[ -2C' - \frac{(k^2+l^2)^2}{R} C + AB \frac{(k^2-l^2)^2}{kl} \right] = 0.
\end{align*}
\]  

(15)

In Eq. (15), the terms \( \cos(ly) \), \( \cos(kx) \), and \( \sin(ly) \sin(kx) \) are linearly independent, so that the coefficients of these terms must separately equal zero.\(^{12}\) This yields

\[
\begin{align*}
\dot{A} &= -\frac{l^2}{R} A + BC \frac{2l^3}{k(k^2+l^2)}, \\
\dot{B} &= -\frac{k^2}{R} B + AC \frac{-2k^3}{l(k^2+l^2)} + C \frac{-2km}{k^2+l^2}, \\
\dot{C} &= -\frac{(k^2+l^2)}{R} C + AB \frac{k^2-l^2}{2kl}
\end{align*}
\]  

(16a)\(\text{ (16b)}\)\(\text{ (16c)}\)

Equations (16) can also be written as

\[
\begin{align*}
\dot{A} &= d_1 A + d_2 BC + d_3 B, \\
\dot{B} &= e_1 B + e_2 AC + e_3 C, \\
\dot{C} &= f_1 C + f_2 AB + f_3 A,
\end{align*}
\]  

(17a)\(\text{ (17b)}\)\(\text{ (17c)}\)

where

\[
\begin{align*}
d_1 &= -\frac{l^2}{R}, & d_2 &= \frac{2l^3}{k(k^2+l^2)}, & d_3 &= 0, \\
e_1 &= -\frac{k^2}{R}, & e_2 &= -\frac{2k^3}{l(k^2+l^2)}, & e_3 &= -\frac{2km}{k^2+l^2}, \\
f_1 &= -\frac{(k^2+l^2)}{R}, & f_2 &= \frac{k^2-l^2}{2kl}, & f_3 &= 0.
\end{align*}
\]  

(18)\(\text{ (19)}\)

Equations (17) are the equations we integrated numerically.

The approximations leading to these equations have been severe, and much of the content of Eq. (11) may have been lost thereby. We do not expect Eqs. (17) to describe real flow to high precision. However, the nonlinearity and dependence on Reynolds number do remain, and we proceed to numerically integrate these equations, with an eye more toward qualitative than quantitative description of real flow.

### B. Numerical integration of equations (Ref. 6)

Given \( A_n, B_n, C_n \) we compute \( \dot{A}, \dot{B}, \dot{C} \):

\[
\begin{align*}
\dot{A}_i &= d_1 A_n + d_2 B_n C_n, \\
\dot{B}_i &= e_1 B_n + e_2 A_n C_n + e_3 C_n, \\
\dot{C}_i &= f_1 C_n + f_2 A_n B_n + f_3 A_n.
\end{align*}
\]  

(20)

From \( \dot{A}_i, \dot{B}_i, \dot{C}_i \) and the time interval \( \Delta t \) we can compute the midpoint \( A_{(n+1)}, B_{(n+1)}, C_{(n+1)} \):

\[
\begin{align*}
A_{(n+1)} &= A_n + \dot{A}_i \Delta t, \\
B_{(n+1)} &= B_n + \dot{B}_i \Delta t, \\
C_{(n+1)} &= C_n + \dot{C}_i \Delta t.
\end{align*}
\]  

(21)

Now we compute \( \dot{A} \)' \( (A_{(n+1)}, B_{(n+1)}, C_{(n+1)}) \), \( \dot{B} \)' \( (A_{(n+1)}, B_{(n+1)}, C_{(n+1)}) \), \( \dot{C} \)' \( (A_{(n+1)}, B_{(n+1)}, C_{(n+1)}) \):

\[
\begin{align*}
\dot{A}_i' &= d_1 A_{(n+1)} + d_2 B_{(n+1)} C_{(n+1)}, \\
\dot{B}_i' &= e_1 B_{(n+1)} + e_2 A_{(n+1)} C_{(n+1)} + e_3 C_{(n+1)}, \\
\dot{C}_i' &= f_1 C_{(n+1)} + f_2 A_{(n+1)} B_{(n+1)}.
\end{align*}
\]  

(22)

Lastly we compute the new point \( A_{n+1}, B_{n+1}, C_{n+1} \):

\[
\begin{align*}
A_{n+1} &= A_n + \frac{\Delta t}{2} (\dot{A}_i + \dot{A}_i'), \\
B_{n+1} &= B_n + \frac{\Delta t}{2} (\dot{B}_i + \dot{B}_i'), \\
C_{n+1} &= C_n + \frac{\Delta t}{2} (\dot{C}_i + \dot{C}_i').
\end{align*}
\]  

(23)

Equations (18)—(23) are the algorithm we used to numerically integrate Eqs. (17).

To preserve the physical validity of the flow characterized by Eqs. (17), some care must be taken in choosing values for the constants \( k \), \( l \), and \( m \). From Schlichting’s discussion of a turbulent boundary layer\(^2\) we use the empirical result that the minimum wavelength of the dis-
In addition, we impose the further restriction that $k^2 > l^2$ so that $f_2 > 0$ in Eqs. (17). As a result, analysis of the eigenvalues of Eqs. (17) is simplified. Lastly our choice, and justification, of the flow function $U$ require $l < 1$ and $n > -l$.

For our study we chose $k = 0.62$, $l = 0.07$, $m = -0.064$. We used $A = 0.01$, $B = 0.01$, $C = 0.01$ as the initial point of the integration; $\Delta t$ was 1.

We used double-precision advanced BASIC on the IBM Personal Computer for calculations and graphic results. We also used double-precision FORTRAN on the University of Rhode Island NAS 7000N mainframe computer for calculations and graphic results.

Typical integrations were carried out for 5000 time units, and we estimated the precision of the numerical calculations by studying the effect of reducing the time step $\Delta t$. After a time 5000 units, $B(5000)$ for $\Delta t = 1$ differed from $B(5000)$ for $\Delta t = \frac{1}{10}$, by about 0.1%.

III. RESULTS

We observed a wide range of qualitative behavior of the solutions of Eqs. (19) corresponding to a range of values of $R$. For $R < 15.5914$, we observed the solutions $A, B, C$ to oscillate regularly (see Fig. 1), the amplitude of oscillations decayed, and the solutions $A, B, C$ approached a

**FIG. 1.** $A, B, C$ vs time for $R = 10$. Time interval between points shown is 40 units.

![Figure 2](image2.png)

**FIG. 2.** $C$ vs time for several values of $R$. Time interval between points shown is 40 units. (a) $R = 16$, 4-cycle; (b) $R = 22$, 8-cycle; (c) $R = 23.4$, 16-cycle; (d) $R = 40$, chaotic.
NONPERIODIC FLOW IN THE NUMERICAL INTEGRATION...

FIG. 3. $A$ vs $C$ for several values of $R$. Time interval between points shown is 10 units, except in (e), where it is 2 units. (a) $R=10$; (b) $R=16$, 4-cycle; (c) $R=22$, 8-cycle; (d) $R=23.4$, 16-cycle; (e) $R=40$, chaotic.
fixed point. For $15.5914 < R < 18$, the solutions oscillate regularly [see Fig. 2(a)], the amplitude does not decay, and the oscillations appear to form a stable 4-cycle (see the following). For $18 < R < 21$, the solutions oscillate irregularly, the amplitude does not decay, and the oscillations appear to be changing from a 4-cycle to an 8-cycle. For $21 < R < 23$, the solutions oscillate regularly [see Fig. 2(b)], the amplitude does not decay, and the oscillations appear to form a stable 8-cycle (see the following). For $R = 23.4$, the solutions oscillate irregularly [see Fig. 2(d)], the amplitude does not decay, and the oscillations appear to be changing from a 4-cycle to an 8-cycle. For $R = 23.5$, the solutions oscillate regularly [see Fig. 2(c)], the amplitude does not decay, and the oscillations appear to form a stable 8-cycle (see the following). For $R = 23.4$, the solutions oscillate irregularly [see Fig. 2(d)], the amplitude does not decay, and the oscillations appear to be chaotic (see the following).

Our judgment as to whether the oscillations are stable $n$-cycles or chaotic derives from considerations of two types of information: the trajectory of the solution in $A, B, C$ space, and the Poincaré section of that trajectory with a plane, $A = \text{const}$.

Figures 3(a)–3(e) show “three-dimensional” portraits of the trajectories of the solutions in $A, B, C$ space. Figure 3(a) shows the spiraling decay of the solutions toward a fixed point for $R = 10$. Figure 3(b) shows that the trajectory for $R = 16$ is stable and consists of two lobes. Figure 3(c) shows that the trajectory for $R = 22$ is stable and consists of four lobes. Figure 3(d) shows that the trajectory for $R = 23.4$ is stable and consists of eight lobes. Figure 3(e) shows that the trajectory for $R = 40$ is not stable and consists of many lobes of various sizes.

In the nomenclature of mappings, a mapping is said to be an “$n$-cycle” if it takes $n$ applications of the mapping to get back to the original point. For instance, a 4-cycle would consist of four points; point 1 would map into point 2, point 2 into point 3, point 3 into point 4, and point 4 back into point 1. Thus, a 4-cycle takes four steps to return to the original point. Trajectories such as those traced by these solutions do not have such a simple structure. It is useful to take the intersection of this three-dimensional trajectory with a two-dimensional surface. The resulting set of intersection points is known as a Poincaré section or Poincaré map, and gives information about the periodicity of the trajectory.

For the two-dimensional surface we chose the plane $A = 0.0116$. (a) $R = 16$, 4-cycle, $2 	imes 10^4 < t < 5 	imes 10^4$; (b) $R = 22$, 8-cycle, $2 	imes 10^4 < t < 5 	imes 10^4$; (c) $R = 23.5$, 16-cycle, $2 	imes 10^4 < t < 2 	imes 10^5$; (d) $R = 40$, chaotic, $2 	imes 10^4 < t < 2 	imes 10^5$.

FIG. 4. Intersection of the trajectory with the plane $A = 0.0116$. (a) $R = 16$, 4-cycle, $2 	imes 10^4 < t < 5 	imes 10^4$; (b) $R = 22$, 8-cycle, $2 	imes 10^4 < t < 5 	imes 10^4$; (c) $R = 23.5$, 16-cycle, $2 	imes 10^4 < t < 2 	imes 10^5$; (d) $R = 40$, chaotic, $2 	imes 10^4 < t < 2 	imes 10^5$. 
iv. Conclusions

The simple mathematical model of a fluid dynamical system gives rise to equations whose numerical solutions behave in qualitatively different ways. This behavior includes decay to constant values, regular oscillation, and chaos. The authors believe these different behaviors resemble the flow of fluids under different circumstances, viz., fluid motion dissipating due to viscous forces, laminar fluid flow, and turbulent flow.

Moon et al. have made a similar study of another equation of fluid dynamics, the Ginzburg-Landau equation. They find periodic and chaotic regimes as the control parameter is varied, just as we do. In addition, the transition to turbulence in their case seems to proceed via the "three-frequency scenario" of Newhouse et al. In other work we will attempt to determine the predicted fluid velocities and their spectra from the functions A, B, C, and from there, to determine which, if any, of the competing paths to chaos our model chooses.

Acknowledgments

The authors wish to thank Dr. Leonard Kahn and Dr. J. Scott Desjardins for many helpful discussions, as well as for the use of Dr. Kahn's Apple computer. One of us (E.X.D.) wishes to acknowledge the support of the International Business Machines Corporation during his educational leave of absence.

Appendix: Choice of Flow Function U

The choice of flow function U is crucial to the behavior of the mathematically modeled dynamical system. Therefore, the flow function was chosen mainly for its physical relevance and for the mathematical advantage it offered. This advantage was realized in that certain terms are discarded and one term retained as a result of our choice, namely:

\[ U_p = \frac{m}{\sin(lp)} \]

We justify our choice as follows. For \( ly \ll 1 \), \( \sin(lp) \approx ly \), so that

\[ U_p \approx \frac{m}{l} \frac{1}{y} \]

Upon integration with respect to y:

\[ U_p \approx \frac{m}{l} \ln|y| + C_1 \]

Upon second integration with respect to y:

\[ U \approx \frac{m}{l} (-y + y \ln|y| + C_1 y + C_2) \]

According to our boundary conditions

\[ U(y) \to 0 \text{ as } y \to 0 \]

and

\[ U(y) \to 1 \text{ as } y \to 1 \]

From the first condition, we deduce that \( C_2 = 0 \). From the second, we deduce that \( C_1 = 1 + 1/m \). We also desire that U reach its maximum value for \( y \geq 1 \). This implies \( C_1 \leq 0 \). From the conditions that \( U(1) = 1 \) and \( C_1 \leq 0 \) and \( l > 0 \), we deduce that

\[ 0 > m \geq -l \]
